# Preface

# About this Book

This book describes the functionality, registers, interfaces, signals, timing specifications, core integration, clocking guidelines, testing and physical design requirements, and the performance and operating environment of the PCI Express x16 Data Link and Logical Physical core.

This document is available to anyone with access to the Design Kit for the core. If you need access, contact your IBM representative.

# Who Should Use this Book

This book is for hardware, software, and application developers who need to understand the PCI Express x16 Data Link and Logical Physical core.

# **Revision Log**

**Note**: Changes from previous versions of this document are marked with blue change bars throughout the text. Italicized text and page numbers in this table are hypertext links. Change bars apply only to the most recent version of the document.

Date	Version	Revision	Page
February 23, 2006	Document Revision 9 This version of the	Updated descriptions of the supported link negotiation features in <i>Section 1.2 Features, Section 2.1 Supported Link Widths,</i> and <i>Table 5 Configuration Interface Signal Descriptions.</i>	9,14, 24
document corre- sponds to core version 4.02 or later.		Updated terminology so that references to <i>Section 5.1.1 Physical Link Width</i> are consistent.	25, 71
October, 2005 Document Revision 8		Core version 4.02 adds the feature described in the new section Section 5.1.5 Use of Synchronous or Asynchronous Set/Reset Flip-Flops.	73
This version of the document corre-	Modified Section 5.1 Configurability to describe the new feature.	71	
	sponds to core version 4.02 or later.	Modified Section 5.2.3 Flip/Flop Selection to describe the new feature.	74
April, 2005	Document	Updated Section 1.4 References.	11
	This version 7 This version of the document corre- sponds to core version 4.00 or later.	Updated Table 7 Training Control Interface Signal Descriptions.	28
		Updated Section 4.4.1.3 Training Control Loopback (Master).	30

Core version 4.02 or later

Date	Version	Revision	
January, 2005	Document Revision 6	Changed compliance level to PCI Express Base Specification 1.1.	Through- out
	This version of the document corre- sponds to core	Added Surprise Down functionality. Updated Section 1.2 Features and Section 4.3 Configuration Interface. Added Section 4.3.3.7 DL_EC08_SURPRISEDOWN.	9, 22, 27
	version 4.00 or later.	Added configurability to PHY interface width of x1. Updated <i>Section 1.2 Features</i> and <i>Section 5.1.1 Physical Link Width</i> . Also updated various references through the document.	9, 71
		Corrected RAM address width vs. physical link width specification in <i>Section 15 Max_Payload_Size versus Replay Buffer Configuration Settings</i> .	71
		Re-worded some text in Section 5.2.1.2 Timing to clarify the timing requirements.	73
September, 2004	Document	Updated Section 1.2 Features to highlight link width configurability.	9
	This version of the	Updated Section 2.1 Supported Link Widths	14
document corre- sponds to core version 3.02 or	document corre- sponds to core version 3.02 or later.	Changed signal SYS_EC0C_MAXLINKWIDTH to SYS_MAXLINKWIDTH in Section 4.3 Configuration Interface and Table 5 Configuration Interface Signal Descriptions	22, 23
		Added new output signal DL_LANESREVERSED to Figure 7 Configuration Inter- face I/O Signals Diagram and Table 5 Configuration Interface Signal Descriptions.	22, 23
	Changed the configuration item "Local NFTS" (described previously in Section 5.1.4) to an input port. See <i>Section 4.3.1 Use of the SYS_MAXLINKWIDTH and SYS_LOCALNFTS Inputs.</i>	24	
	Updated <i>Section 4.4.1.2 Training Control Reset</i> to describe the expanded behavior of the SYS_TCTX_RESET input when the core is in the L2 link state.	30	
		Added Section 4.9.1 PHY Requirements to Support Exit from the L2/3 Ready Link State to describe the core requirements if a link state transition from L2 back to Detect is required.	64
	Updated Section 4.10.2 Reading TLP Data from a Replay Buffer Configured for One-Cycle Access	66	
	Added additional configuration parameter: 2 Cycle Replay Access. See changes in <i>Section 4.10.3 Reading TLP Data from a Replay Buffer Configured for Two-Cycle Access</i> and <i>Section 5.1.3 Replay Buffer Read Access Time</i> .	67, 72	
		Update Section 5 Core Integration	71
		Update Section 5.1.3 Replay Buffer Read Access Time	72
		Modified allowed range of the PCIEXDLP_LOSTIMEOUT configuration parameter and corrected typo in <i>Section 5.1.4 Los Entry Timeout Setting</i> .	73
		Added additional entry to <i>Table 16 Asynchronous Capture Flip-Flop Pairs in the Design</i> .	74

Date	Version	Revision	
June, 2004	Document Revision 4	NOTE: This version of the databook is Preliminary. Customers should NOT appe out with this version of the core.	
	This version of the document corre- sponds to core version 3.00 or	Added DL_INBANDPRESENCE core output to <i>Figure 7</i> and <i>Table 5</i> . Revised <i>Section 4.3.2 DL_INBANDPRESENCE and DL_LINKUP</i> and <i>Figure 8</i> to include a description of this new signal.	22, 23
	later.	Corrected text in <i>Section 4.7.2 Initializing Flow Control for a Virtual Channel</i> which describes operation of the flow control interfaces while in link power management states.	46
		Fixed typo in <i>Table 12 PHY Interface Signal Descriptions</i> ; PHY_RXVALID should be RXVALID.	60
		Inserted a new Section 5.1.1 Physical Link Width before the existing 5.1.1 to describe a new configuration option. Also modified the following to accommodate the new configuration option: Section 5.1.2 Replay Buffer Size Section 4.5 TLP Transmit Interface Section 4.6 TLP Receive Interface Section 4.9 PHY Interface Section 4.10 TLP Replay Interface Section 4.11 Loophack Interface	71
March 2004	Document	Undated Eigure 1 PCI Express Core Application	11
Revision 3 This version of the		Corrected signal count in Figure 3 I/O Signal Diagram and Figure 43 PHY Interface Signal Diagram.	
	sponds to core	Added Section 4.5.4 Transmit TLP Length Considerations.	37
later.	Updated text in <i>Section 4.6.2 TLP Receive Interface Protocol</i> to describe behavior when 1 and 2 DWord TLPs are received.	40	
		Updated <i>Section 4.7 Flow Control Interface</i> to reflect a change to the Flow Control Initialization interface.	43
		Added a note to the end of Section 4.7.2 Initializing Flow Control for a Virtual Chan- nel.	46
		Corrected reference to TL_FCU_REQUEST in <i>Section 4.7.3 Transmitting Flow Con-</i> <i>trol Update Information.</i>	47
		Added description of ASPM and PCI-PM L1 exit conditions to Section 4.8.2.3 Exiting the ASPM L1 Link State and Section 4.8.3.3 Exiting the PCI-PM L1 Link State.	54, 55
		Updated section <i>Section 5.1 Configurability</i> to reflect an enhancement made to the Replay Buffer size selection controls.	71
		Added text and Table 16 Asynchronous Capture Flip-Flop Pairs in the Design to Section 5.2.1.2 Timing.	74
November, 2003	Document Revision 2 This version of the document is released with the Full Design Kit (FDK) and corre- sponds to core version 1.00 or later.	Full Design Kit publication (Previous document versions were for preliminary publication only.)	_
September, 2003	Preliminary Copy - Revision 1	Updated entire book.	-
September, 2003	Preliminary Copy	Initial release	-

# 1. Overview

# 1.1 Introduction

The PCI Express x16 Data Link and Logical Physical (PCIEX16DLP) core provides the majority of the functionality of the PCI Express data link and logical physical layers. It can be used to implement all types of PCI Express devices: root ports, switch ports, bridge PCI Express ports, and endpoints.

# 1.2 Features

- Supports the PCI Express Base Specification, Revision 1.1
- Compatible with the industry standard *PHY Interface for PCI Express Architecture* (PIPE) specification, version 1.00
- Can be configured to support PHY interface widths of x1, x4, x8, or x16
- Supports x1, x4, x8, and x16 negotiated link widths (limited by configured physical interface width)
- Supports all defined TLP packet sizes
- Provides the following data link and logical physical layer functions:
  - Link width negotiation to x1, x4, x8, and x16 link widths (limited by the configured physical link width)
  - Automatic receiver polarity reversal
  - Multi-lane receive data deskew
  - Data scrambling
  - Upstream or downstream port configurability
  - Link training features supported as a downstream facing port:
    - Generation of link reset, link disable, loopback, and scrambling disable
    - Reception of loopback and scrambling disable
  - Link training features supported as an upstream facing port:
    - Generation of loopback and scrambling disable
    - Reception of link reset, disable, loopback, and scrambling disable
  - Advanced error checking and reporting
  - Active state power management: Link states L0s and L1
  - PCI power management: Link states L1 and L2/3 ready
  - DLLP assembly/disassembly with CRC generation and checking
  - TLP sequence number and LCRC generation and checking
  - Surprise Down error detection

- Contains the following interfaces:
  - TLP transmit (data bus width depends on selected PHY interface width)
  - TLP replay buffer (external 1-port RAM required, data bus width depends on selected PHY interface width)
  - TLP receive (data bus width depends on selected PHY interface width)
  - Flow control initialization and update
  - Power management
  - PCI Express configuration space supports advanced error reporting
- Projected target libraries: 0.13  $\mu m$

# **1.3 Typical Application**

*Figure 1 on page 11* shows the total available IBM PCI Express solution. The PCI Express Protocol Wrapper core can be configured to include the protocol layers and functionality required for your application, and the PIPEPHY wrapper core can be configured to link widths of x1, x4, x8, and x16. Contact your IBM representative for additional information about configurations available for your application.

#### PCI Express x16 Data Link and Logical Physical

## 1.4 References

- PCI Express Base Specification, Revision 1.1, March 28, 2005
- PHY Interface for PCI Express Architecture, Version 1.00, June 19, 2003
- PCI Express x16 PHY Interface, IBM Document Number SA15-5766-00
- PCI Express x16 Transaction Layer, IBM Document Number SA15-5770-00

# **1.5 Additional Required Elements**

The following additional elements are required to use this core:

- 1-port synchronous RAM (or equivalent)
- PIPE version 1.00 compliant PHY

# 1.6 Related IBM Cores

The IBM PCI Express PIPE PHY Wrapper core can be used to provide PIPE version 1.0 compliant PHY functionality.

Contact your IBM representative for additional information on this core and other IBM products.

# 1.7 Conventions

- All data and register content in this document is referred to in little endian format to match the notation used in the *PCI Express Base Specification*.
- All data sizes in this document are defined as:
  - Byte 8 bits
  - Word 16 bits
  - Double-word 32 bits
- Signal timings are calculated from the rising edge of the appropriate clock.

PCI Express x16 Data Link and Logical Physical

# 2. Functional Description

## Figure 2. Core Block Diagram

The PCIEX16DLP core enables transaction layer packet (TLP) communication across a PCI Express link and control and maintenance of the link. A block diagram of the core is shown in *Figure 2*.

Each of the defined interfaces is explained in detail in *Section 4 Hardware Interface* on page 17.

# 2.1 Supported Link Widths

The core supports negotiated link widths of x1, x4, x8, and x16 (limited by the core's configured physical link width). In addition, it supports automatic lane reversal when the negotiated link width is the same as the core's configured physical link width. See *Section 5.1.1 Physical Link Width* on page 71 for more information on configuring the physical link width.

# 2.2 TLP Transmit and Receive Latency

*Table 1* shows the best-case latency for the TLP transmit and receive paths through this core. For a more detailed explanation, see *Section 4.5.1*, *TLP Transmit Latency, on page 33* and *Section 4.6.1, TLP Receive Latency, on page 39*.

## Table 1. Best Case TLP Latency

Direction	Latency (Clock Cycles)
Transmit	3
Receive	5

# 3. Software Interface

The core does not contain any user accessible registers, and therefore does not have a defined software interface.

# 4. Hardware Interface

The core uses several interfaces to perform its functions. A top-level interface block diagram in shown in *Figure 3 on page 18*. Each interface is described in detail in subsequent sections.

Port names have a prefix which designates the source of the signal. The convention is:

PCLK250	250 MHz system clock.
SYS_name	Signals supplied by user logic. Signals of this type which may be sourced by VDD or GND are noted.
DL_ <i>name</i>	Signals driven by this core. Most connect to transaction layer logic or configuration logic, but some can be used by user logic.
TL_ <i>name</i>	Signals supplied by transaction layer logic.
CFG_name	Signals supplied by configuration logic.
TIE0_ <i>name</i>	Signals which <i>must</i> be sourced by GND.

Each signal also has a timing associated with it. The meaning of each is as follows:

Async	The signal is asynchronous (has no defined timing relationship to any clock).
Clock	The signal is a clock. The frequency will be specified.
Begin	Inputs to the core: The setup time is 85% of the referenced clock cycle.
	Outputs: The valid time is 15% of the referenced clock cycle.
Early	Inputs to the core: The setup time is 75% of the referenced clock cycle.
	Outputs: The valid time is 25% of the referenced clock cycle.
Middle	Inputs to the core: The setup time is 50% of the referenced clock cycle.
	Outputs: The valid time is 50% of the referenced clock cycle.
Late	Inputs to the core: The setup time is 25% of the referenced clock cycle.
	Outputs: The valid time is 75% of the referenced clock cycle.

# 4.1 Signal Diagram

## Figure 3. I/O Signal Diagram

# 4.2 System Interface

The system interface consists of signals that control the clocking, reset, and simulation speed of the core. The timing of the signals and their asserted level (if any) are noted in their descriptions.

#### Figure 4. System Interface I/O Signals Diagram

Signal Name	Туре	Timing	Description
PCLK250	Input	Clock	250 MHz clock. Sourced from the PHY layer (the PIPE PCLK signal).
SYS_RESETN	Input	Async	This signal is active low. It should be the same signal connected to the RESET# input of the PHY. Asserting this signal causes a core reset to occur. Typically this signal is asserted during system power-up. It may be asserted and deasserted asynchronously.
DL_PGRESET	Output	Early	This signal is active high. It is a partially synchronized version of the SYS_RESETN signal which must be used by the Transaction Layer and Configuration Register logic to return all logic to a Power-On state. It is asserted asynchronously with the assertion of SYS_RESETN, but deasserted synchronously after SYS_RESETN has been deasserted and the PHY has reported that it is operational.
DL_HOTRESET	Output	Early	This signal is active high. It is a synchronous signal that is asserted when the core is configured as an upstream facing port and is receiving "Hot Reset" signalling from upstream. It is not asserted when the core is configured as a downstream facing port.
TIE0_SIMSPEED	Input	N/A	This signal must be tied to GND. It is provided to reduce simulation time spent during link training. See <i>Section 4.2.2, Hot Reset</i> ( <i>DL_HOTRESET</i> ), <i>on page 20</i> for more information.

#### **Table 2. System Interface Signal Descriptions**

## 4.2.1 Power-Good Reset (DL\_PGRESET)

A power-good reset proceeds as follows (see Figure 5 on page 20):

- 1. The device is powered on.
- 2. SYS\_RESETN is asserted.
  - The minimum assertion time of SYS\_RESETN is determined by the minimum assertion time of the asynchronous set/reset pins of the targeted flip-flops in the library used for synthesis. Typically, the minimum time is less than 10 ns, but note that the PHY may require a much longer time. It is the user's responsibility to ensure that the requirements are met.
  - This signal should also drive the RESET# input of the attached PHY.
  - The DLP core asserts DL\_PGRESET asynchronously with the assertion of SYS\_RESETN.
  - The attached PHY asserts its PHYSTATUS output to indicate that it is initializing.
- 3. SYS\_RESETN is deasserted.
  - Before SYS\_RESETN is deasserted, the attached PHY must drive its PCLK output (this core's PCLK250 input) to either a '0' or '1' level. PCLK does not, however, have to be running at this time.
- 4. The attached PHY completes its initialization process and informs the core that it is ready for normal function by deasserting PHYSTATUS.
  - Before deasserting PHYSTATUS, the attached PHY must be driving its PCLK output (this core's PCLK250 input) at 250 MHz +/- 300 ppm, not including any spread spectrum clocking effects.
- 5. The core deasserts DL\_PGRESET synchronously with a rising edge of PCLK250 eight clock cycles after PHYSTATUS was sampled as deasserted.
  - All PCI Express logic, including transaction layer logic, configuration register logic, and any user logic that uses the PCLK250 clock source, must reset when DL\_PGRESET is asserted. This ensures that all logic using the PCLK250 clock is reset at the same time.

## 4.2.2 Hot Reset (DL\_HOTRESET)

A hot reset proceeds as follows (see *Figure 6*):

- 1. The port is configured as a downstream component (upstream facing port) and has negotiated a link.
- 2. The upstream component asserts hot reset signalling on the link.
  - Hot reset is signalled with the training control feature of TS1/2 ordered sets. See the *PCI Express Base Specification* for more information.
  - The core asserts DL\_HOTRESET when it recognizes the assertion of hot reset signalling.
- 3. The upstream component deasserts hot reset signalling on the link.
  - The core deasserts DL\_HOTRESET when it recognizes the deassertion of hot reset signalling.
  - The core will attempt to re-establish a link after hot reset signalling is deasserted.

#### Figure 6. Timing Diagram for Hot Reset

PCLK250			
Link RX	Normal Operation	Hot Reset	Electrical Idle
DL_HOTRESET		/	———— —————————————————————————————————
		Assertion of Hot Reset Recognized	Deassertion of Hot Reset Recognized

## 4.2.3 Use of TIE0\_SIMSPEED to Improve Simulation Throughput

**TIE0\_SIMSPEED must be tied to GND.** It is provided as a simulation aid only. It may be forced to VDD by a simulator to reduce timeouts and the number of training ordered sets transmitted by the core in the various link training states.

#### PCI Express x16 Data Link and Logical Physical

*Table 3* describes the timeouts for link training states as specified by the *PCI Express Base Specification* and the resulting timeout when TIE0\_SIMSPEED has been forced to VDD. Link training states which do not appear in the table do not have a timeout associated with them and therefore are not affected by TIE0\_SIMSPEED.

Link Training State	Timeout Specified by PCI Express	Timeout when TIE0_SIMSPEED is Forced to VDD
Detect.Quiet	12 ms	2 μs
Detect.Active	12 ms	2 µs
Polling.Active	24 ms	4 μs
Polling.Configuration	48 ms	4 μs
Polling.Speed	2 ms	2 μs
Configuration.Linkwidth.Start	24 ms	4 μs
Configuration.Linkwidth.Accept	2 ms	2 μs
Configuration.Lanenum.Wait	2 ms	2 μs
Configuration.Complete	2 ms	2 µs
Configuration.Idle	2 ms	2 μs
Recovery.RcvrLock	24 ms	4 μs
Recovery.RcvrCfg	48 ms	4 μs
Recovery.Idle	2 ms	2 µs
RX_L0s.FTS	< 32 *[N_FTS+3] ns > 16*[N_FTS+3] ns	32*[N_FTS+2] ns
RX_L0s.FTS (Extended Sync)	< 65 μs > 32 μs	2 μs
Disabled	2 ms	2 μs
Loopback.Entry	2 ms	2 µs
Loopback.Exit	2 ms	2 μs
HotReset	2 ms	2 μs

## Table 3. Timeouts Controlled by TIE0\_SIMSPEED

*Table 4* describes the minimum number of TS1 or TS2 ordered sets transmitted in the link training states as specified by the *PCI Express Base Specification* and the resulting number when TIE0\_SIMSPEED has been forced to VDD. Link training states that do not appear in the table, either do not cause TS1 or TS2 ordered sets to be transmitted or do not have a specified minimum and therefore are not affected by TIE0\_SIMSPEED.

## Table 4. Number of Ordered Sets Controlled by TIE0\_SIMSPEED (Page 1 of 2)

Link Training State	Number of Ordered Sets Specified by PCI Express	Number of Ordered Sets When TIE0_SIMSPEED is Forced to VDD
Polling.Active	1024	48
Polling.Configuration	16	16
Configuration.Complete	16	16
Configuration.Idle	16	16

Link Training State	Number of Ordered Sets Specified by PCI Express	Number of Ordered Sets When TIE0_SIMSPEED is Forced to VDD	
Recovery.RcvrLock (Extended Sync)	1024	48	
Recovery.RcvrCfg	16	16	
TX_L0s.FTS	N_FTS	N_FTS	
Disabled	16	16	

#### Table 4. Number of Ordered Sets Controlled by TIE0\_SIMSPEED (Page 2 of 2)

# 4.3 Configuration Interface

The configuration interface defines the configuration of the PCI Express device using this core. It is also used to report the state of the link.

All input signals, except as noted, must be synchronous to the rising edge of PCLK250. All output signals are synchronous to the rising edge of PCLK250. All signals that are defined to have an asserted state are considered positive-active; meaning that their asserted level is a logical '1'.

Signal Name	I/О Туре	Timing	Description
SYS_EC00_PORTTYPE(3:0)	Input	Begin	This signal is the Device/Port Type field of the PCI Express Capabili- ties register. It may be driven by VDD/GND. If not driven by VDD/GND, it must be stable after SYS_RESETN is deasserted. Its setting must be equivalent to that of the Device/Port Type field reported by the configu- ration logic of the port.
SYS_MAXLINKWIDTH(5:0)	Input	Begin	This signal defines the maximum link width that the core attempts to negotiate. It may be driven by VDD/GND. If not driven by VDD/GND, it must not be changed after SYS_RESETN is deasserted. Its setting must be less than or equal to the Maximum Link Width defined in the Link Capabilities Register of the port. See Section 4.3.1 Use of the SYS_MAXLINKWIDTH and SYS_LOCALNFTS Inputs on page 24 for more information. Note: This signal does not exist when the core is configured for a x1 Physical Link Width.
SYS_LOCALNFTS(7:0)	Input	Begin	This signal defines the number of FTS ordered sets required by the local device's receiver to exit the L0s state. It may be driven by VDD/GND. If not driven by VDD/GND, it must not be changed after SYS_RESETN is deasserted. See Section 4.3.1 Use of the SYS_MAXLINKWIDTH and SYS_LOCALNFTS Inputs on page 24 for more information.
CFG_EC08_MAX_PAYLOAD_SIZE(2:0)	Input	Early	This signal is the Maximum Payload Size field in the Device Control register. It may be driven by VDD/GND. Its setting must be equivalent to that of the Maximum Payload Size field reported by the configura- tion logic of the port.
CFG_EC10_LINKPMCONTROL(1:0)	Input	Early	This signal is the Active State Link PM Control field of the Link Control register. This signal must be driven by registers which reflect the Active State Link PM Control field of the Link Control register.
CFG_EC10_RETRAINLINK	Input	Early	A link retrain may be initiated by driving this signal to '1' for one cycle. It may be generated from the Retrain Link bit in the Link Control regis- ter. <b>Note:</b> The Retrain Link bit of the Link Control register is reserved for upstream facing port types, and so this input must be driven by GND in that case.
CFG_EC10_EXTENDEDSYNCH	Input	Early	This signal is the Extended Synch bit of the Link Control Register. It must be driven by a register which reflects the Extended Synch bit of the Link Control register.
SYS_EC14_HOTPLUG_SURPRISE	Input	Early	This signal is the Hot-Plug Surprise bit of the Slot Capabilities Regis- ter. It must be driven by VDD/GND or a register which reflects the Hot- Plug Surprise bit of the Slot Capabilities Register.
SYS_EC14_HOTPLUG_CAPABLE	Input	Early	This signal is the Hot-Plug Capable bit of the Slot Capabilities Regis- ter. It must be driven by VDD/GND or a register which reflects the Hot- Plug Capable bit of the Slot Capabilities Register.
CFG_EC18_PWR_CTL_CONTROL	Input	Early	This signal is the Power Controller Control bit of the Slot Control Reg- ister. It must be driven by a register which reflects the Power Controller Control bit of the Slot Control Register.
TL_EC10_LINKACTIVE	Input	Early	This signal from transaction layer logic must be driven to '1' when VC0 flow control negotiation is complete. It indicates that the link is capable of transmitting and receiving TLPs.
DL_EC10_NEGLINKWIDTH(5:0)	Output	Early	This signal is the link width established by the core when link negotia- tion has completed. It may be used as the Negotiated Link Width field of the Link Status register.

# Table 5. Configuration Interface Signal Descriptions (Page 1 of 2)

## Table 5. Configuration Interface Signal Descriptions (Page 2 of 2)

Signal Name	I/O Type	Timing	Description
DL_EC10_LINKTRAINING	Output	Early	This signal is asserted when link training is in progress. It may be used as the Link Training bit of the Link Status register.
DL_EC08_BADDLLP	Output	Early	This signal is asserted for one cycle when the core has detected a bad DLLP. It may be used to set the Bad DLLP Status bit of the Correct- able Error Status register.
DL_EC08_BADTLP	Output	Early	This signal is asserted for one cycle when the core has detected a bad TLP. It may be used to set the Bad TLP Status bit of the Correctable Error Status register.
DL_EC08_RECEIVERERROR	Output	Early	This signal is asserted for one cycle when the core has detected a Receiver Error. It may be used to set the Receiver Error Status bit of the Correctable Error Status register.
DL_EC08_REPLAYROLLOVER	Output	Early	This signal is asserted for one cycle when the REPLAY_NUM counter rolls over and a link retrain is initiated. It may be used to set the REPLAY_NUM Rollover Status bit of the Correctable Error Status reg- ister.
DL_EC08_REPLAYTIMEOUT	Output	Early	This signal is asserted for one cycle when the REPLAY_TIMER times out and a replay is initiated. It may be used to set the Replay Timer Timeout Status bit of the Correctable Error Status register.
DL_EC08_DLLPE	Output	Early	This signal is asserted for one cycle when a data link protocol error has been detected. It may be used to set the Data Link Protocol Error Status bit of the Uncorrectable Error Status register.
DL_EC08_SURPRISEDOWN	Output	Early	This signal is asserted for one cycle when a link surprise down event has been detected. It may be used to set the Surprise Down Error Sta- tus bit of the Uncorrectable Error Status register.
DL_LINKUP	Output	Early	This signal is asserted when the core has established a link with a remote component.
DL_INBANDPRESENCE	Output	Early	This signal is asserted when the core has detected that a remote component is connected to the port.
DL_LANESREVERSED	Output	Early	<ul> <li>This signal is asserted when the core has negotiated a link with lane reversal. When not asserted, the link's Lane 0 is mapped to PIPE lane</li> <li>0. When asserted, Lane 0 is mapped to the highest numbered PIPE lane:</li> <li>PIPE Lane 3 when the core is configured for a physical link width of x4</li> <li>PIPE Lane 7 when the core is configured for a physical link width of x8</li> <li>PIPE Lane 15 when the core is configured for a physical link width of x16</li> </ul>

## 4.3.1 Use of the SYS\_MAXLINKWIDTH and SYS\_LOCALNFTS Inputs

SYS\_MAXLINKWIDTH and SYS\_LOCALNFTS are used to define link configuration parameters.

#### 4.3.1.1 SYS\_MAXLINKWIDTH

The SYS\_MAXLINKWIDTH input defines the maximum link width that the core attempts to configure during link negotiation. The possible settings vary based on the Physical Link Width configuration parameter (see *Section 5.1.1 Physical Link Width* on page 71) and are shown in *Table 6* on page 25.

#### Table 6. Possible Settings of SYS\_MAXLINKWIDTH

Configured Physical Link Width	Possible Settings of SYS_MAXLINKWIDTH
x1 - PCIEXD_LINKWIDTH_X1	N/A
x4 - PCIEXD_LINKWIDTH_X4	6'b00001 - x1 6'b000100 - x4
x8 - PCIEXD_LINKWIDTH_X8	6'b00000 - x1 6'b00100 - x4 6'b001000 - x8
x16 - PCIEXD_LINKWIDTH_X16	6'b00001 - x1 6'b00100 - x4 6'b01000 - x8 6'b010000 - x16

**Note:** The Maximum Link Width field of the Link Capabilities Register of the port must always report a value equal to or larger than the largest SYS\_MAXLINKWIDTH setting to be used.

#### 4.3.1.2 SYS\_LOCALNFTS

SYS\_LOCALNFTS defines the number of FTS ordered sets required by the local device's receiver to exit the L0s link state. This value is advertised to the port at the other end of the link during link configuration and affects the operation of this core's Replay Timeout logic and Receiver L0s exit timeout logic.

The value of SYS\_LOCALNFTS must account for the number of FTS ordered sets required by this core (one) and the number of FTS ordered sets required by the PHY attached to this core. As an example, if the PHY requires six FTS ordered sets, SYS\_LOCALNFTS should be set to at least seven. Using a value too small to allow the PHY and this core to synchronize, results in the entire link being retrained (which takes more time to complete than the transmission of additional FTS ordered sets).

The equivalent time required to transmit the FTS ordered sets specified by SYS\_LOCALNFTS should also be reflected in the L0s exit latency field of the link capabilities register of the local device. The time is  $(SYS\_LOCALNFTS + 1) * 16 \text{ ns.}$ 

The SYS\_LOCALNFTS input is an 8-bit signal and must be set to a value of 1 to 255.

## 4.3.2 DL\_INBANDPRESENCE and DL\_LINKUP

The DL\_INBANDPRESENCE and DL\_LINKUP signals correspond to the "In-Band Presence" and "LinkUp" columns of Table 4-4 in the *PCI Express Base Specification*.

The DL\_INBANDPRESENCE signal describes the presence detect status of the port. When asserted, the port is connected to a remote port. Note that having a connection does not mean that a link has been established or can be established. This signal is intended for use in downstream facing ports (although it exists and will be driven when this core is configured as either a downstream or upstream facing port) as a way of indicating the presence of an adapter in a slot. Also see the description of the Presence Detect State bit in the Slot Status Register in the *PCI Express Base Specification* for more information on usage of this signal.

The DL\_LINKUP signal describes the state of the link. When deasserted this signal indicates that there is currently no link established with a remote port. All TLP and DLLP interfaces are non-operational. This means that transaction layer logic must not attempt to transmit any TLPs or DLLPs and no TLPs or DLLPs will be received. When DL\_LINKUP changes from a deasserted state to an asserted state, the transaction layer logic must initialize flow control for VC0 before attempting to transmit any TLPs or DLLPs (other than those required to initialize VC0). The core does not contain an interlock to prevent such actions from taking place.

DL\_INBANDPRESENCE and DL\_LINKUP are deasserted when SYS\_RESETN is asserted. Their normal behavior after reset is shown in *Figure 8*:

## Figure 8. DL\_INBANDPRESENCE and DL\_LINKUP After Reset

## 4.3.3 Error Reporting

The core provides output signals that can be used to implement standard and/or advanced error reporting for the port. The following sections define the output signals and the detected errors reported by each.

## 4.3.3.1 DL\_EC08\_RECEIVERERROR

This signal is asserted for one PCLK250 cycle when a receiver error is detected. A receiver error is defined as one or more of the following conditions:

- Any error condition detected in the data stream of any enabled lane and reported by the attached PHY. This includes 8b/10b decode/disparity errors, elastic FIFO overflow/underflow errors, and loss of symbol lock.
- A framing error during reception of a TLP or DLLP. This includes at least:
  - STP/SDP/END/EDB symbols received on lanes of a multi-lane link which are not defined to be valid lanes on which to transmit those symbols
  - END symbol received without a corresponding STP/SDP symbol
  - EDB symbol received without a corresponding STP symbol
  - Two SDP symbols received in one symbol time on a multi-lane link
  - Two STP symbols received in one symbol time on a multi-lane link
- A lane-to-lane deskew error on a multi-lane link. This includes detection of a COM symbol not received on all lanes in the same symbol time, and detected skew larger than five symbol times.

## 4.3.3.2 DL\_EC08\_BADDLLP

This signal is asserted for one PCLK250 cycle when a bad DLLP is received. A bad DLLP is defined as a DLLP that was received without a receiver error but which fails the CRC check.

### 4.3.3.3 DL\_EC08\_BADTLP

This signal is asserted for one PCLK250 cycle when a bad TLP is received. A bad TLP is defined as a TLP that was received without a receiver error, but which fails the CRC check; or, a TLP which was received outof-order (the sequence number does not correspond to the next expected one or one previously received).

## 4.3.3.4 DL\_EC08\_REPLAYROLLOVER

This signal is asserted for one PCLK250 cycle for every four times that the contents of the replay buffer has been retransmitted.

### 4.3.3.5 DL\_EC08\_REPLAYTIMEOUT

This signal is asserted for one PCLK250 cycle when the core has not received an Ack or Nak DLLP for the REPLAY\_TIMER timeout period defined in the *PCI Express Base Specification*. The timeout period varies with the negotiated link width and the value of the CFG\_EC08\_MAX\_PAYLOAD\_SIZE input.

### 4.3.3.6 DL\_EC08\_DLLPE

This signal is asserted for one PCLK250 cycle when an Ack or Nak DLLP is received, but the specified sequence number does not match the last acknowledged sequence number or a currently outstanding sequence number.

### 4.3.3.7 DL\_EC08\_SURPRISEDOWN

This signal is asserted for one PCLK250 cycle when the link is dropped unexpectedly. It is asserted when the core is operating as a downstream facing port, the TL\_EC10\_LINKACTIVE input is asserted, and DL\_LINKUP is de-asserted (indicating the link has been dropped) except in the following cases:

- The link was directed to the Disabled state. See Section 4.4.1.1 Training Control Disable on page 29.
- The link was directed to the Hot Reset state. See *Section 4.4.1.2 Training Control Reset* on page 30.
- The link was directed to the L2 state.
- The Hot-Plug Surprise bit of the Slot Capabilities Register is '1'.
- The Hot-Plug Capable bit of the Slot Capabilities Register is '1' and the Power Controller Control bit of the Slot Control Register is '1' (indicating that power is off to the slot).

.This signal can be used to set the Surprise Down Error Status bit of the Uncorrectable Error Status Register.

## 4.4 Training Control Interface

The Training Control Interface of the core may be used to initiate PCI Express training control features. It is also used to report training control status.

When configured as a downstream facing port, the following features may be initiated:

- Hot Reset
- Disable Link
- Disable Scrambling
- Loopback

and the following conditions are reported:

- Link Disabled
- Loopback
- Scrambling Disabled

When configured as an upstream facing port, the following features may be initiated:

- Disable Scrambling
- Loopback

and the following conditions are reported:

- Link Disabled
- Loopback
- Scrambling Disabled

**Note:** When configured as an upstream facing port, reception of the 'Hot Reset' training control feature is reported with the DL\_HOTRESET core output described in *Section 4.2, System Interface, on page 18.* As a result, it does not appear in this interface.

All input signals, except as noted, must be synchronous to the rising edge of PCLK250. All output signals are synchronous to the rising edge of PCLK250. All signals that are defined to have an asserted state are considered positive-active; meaning that their asserted level is a logical '1'.

## Figure 9. Training Control Interface I/O Signals Diagram

## Table 7. Training Control Interface Signal Descriptions

Signal Name	I/O Type	Timing	Description
SYS_TCTX_RESET	Input	Early	Assert this signal when the core is configured as a downstream facing port (root port, etc) and the hierarchy below the port is to be reset. Normally, this signal should be driven by the Secondary Bus Reset bit of the Bridge Control register.
SYS_TCTX_DISABLE	Input	Early	Assert this signal when the core is configured as a downstream facing port (root port, etc) and the device attached to the port is to be disabled. Normally, this signal should be driven by the Link Disable bit of the Link Control register.
SYS_TCTX_LOOPBACK	Input	Early	Assert this signal when the core is configured as either an upstream or down- stream facing port and loopback mode is desired. The source of this signal is application specific. See <i>Section 4.4.1.3 Training Control Loopback (Master)</i> on page 30 for more information.
SYS_TCTX_SCRAMBLEOFF	Input	Early	Assert this signal when the core is configured as either an upstream or down- stream facing port and scrambling should be disabled on the link. The source of this signal is application specific. It must be asserted before the link is configured to be effective.
DL_TCRX_DISABLE	Output	Early	Status output. Asserted when the link is in the Disabled state.
DL_TCRX_LOOPBACK	Output	Early	Status output. Asserted when the link is in the Loopback state.
DL_TCRX_SCRAMBLEOFF	Output	Early	Status output. Asserted when a link has been established with scrambling disabled.

### 4.4.1 Training Control Priorities

SYS\_TCTX\_RESET, SYS\_TCTX\_DISABLE, SYS\_TCTX\_LOOPBACK, and SYS\_TCTX\_SCRAMBLEOFF may be asserted at any time. However, the core conforms to the *PCI Express Base Specification* and will not assert more than one training control bit at any given time. The signalling priority is:

- 1. SYS\_TCTX\_DISABLE
- 2. SYS\_TCTX\_RESET
- 3. SYS\_TCTX\_LOOPBACK
- 4. SYS\_TCTX\_SCRAMBLEOFF

#### 4.4.1.1 Training Control Disable

Asserting SYS\_TCTX\_DISABLE causes a downstream-facing port to disable the link if a link is being negotiated or is currently operational. The link remains disabled until SYS\_TCTX\_DISABLE is deasserted. An attached device cannot be reset with SYS\_TCTX\_RESET while the link is disabled.

#### Figure 10. Training Control Disable

## 4.4.1.2 Training Control Reset

Asserting SYS\_TCTX\_RESET causes a downstream facing port to initiate the Hot Reset link protocol and resets the hierarchy attached to the port.

If both SYS\_TCTX\_RESET and SYS\_TCTX\_DISABLE are asserted, the link is disabled.

**Note:** Asserting SYS\_TCTX\_RESET when the core is in the PCI-PM L2/L3 ready link state (signalled with DL\_PM\_INL23) causes the core to exit that link state and attempt to negotiate a link. See *Section 4.9.1 PHY Requirements to Support Exit from the L2/3 Ready Link State* on page 64 for additional requirements on PCLK250 and PHYSTATUS.

### Figure 11. Training Control Reset (Hot Reset)

### 4.4.1.3 Training Control Loopback (Master)

Asserting SYS\_TCTX\_LOOPBACK causes the port (both upstream and downstream facing configurations) to enter the loopback master mode if at least one lane has detected a receiver when a link is being negotiated. It is recommended that SYS\_TCTX\_LOOPBACK be asserted before SYS\_RESETN is deasserted. SYS\_TCTX\_LOOPBACK can be asserted after SYS\_RESETN is deasserted, but it is not possible to predict when loopback will be entered and undesirable system effects could occur. For example, if a link has been established and transactions are in-progress when SYS\_TCTX\_LOOPBACK is asserted, loopback mode will be entered (a link down condition) and the transactions will not be completed. The link remains in loopback mode until SYS\_TCTX\_LOOPBACK is deasserted at which time it is renegotiated. See *Section 4.11, Loopback Interface, on page 68* for more information.

#### 4.4.1.4 Training Control Disable Scrambling

Asserting SYS\_TCTX\_SCRAMBLEOFF causes either a downstream- or upstream-facing port to disable scrambling on the link during link configuration as long as SYS\_TCTX\_RESET, SYS\_TCTX\_DISABLE, and SYS\_TCTX\_LOOPBACK are deasserted. It has no effect once a link has been configured. To ensure that scrambling will be turned off, it is recommended that it be asserted before SYS\_RESETN is deasserted when performing a full reset, or before DL\_HOTRESET is deasserted when configured as an upstream-facing port and a Hot Reset is being received.

### Figure 13. Disabling Scrambling During Reset

SYS_RESETN			
SYS_TCTX_SCRAMBLEOFF			
PCI Express Link	Down	Config in progress	Scrambling Disabled

# 4.5 TLP Transmit Interface

The TLP transmit interface is used to transmit TLPs on the link.

**Note:** Some of this interface's signals are affected by the Physical Link Width configuration option. See *Section 5.1.1 Physical Link Width* on page 71 for more information.

The core assigns each TLP a sequence number and while transmitting it also saves it in the replay buffer. When a TLP is acknowledged by the remote component, it is removed from the replay buffer. When the core receives a negative acknowledgement, all TLPs in the replay buffer are re-transmitted as soon as any inprogress TLP or DLLP has been transmitted.

The core can store up to eight unacknowledged TLPs in the replay buffer at any one time.

If the link goes down (indicated by the deassertion of DL\_LINKUP), all TLPs which were accepted for transmission by the core but not acknowledged by the remote component (i.e. all TLPs in the replay buffer), are considered lost.

All input signals must be synchronous to the rising edge of PCLK250. All output signals are synchronous to the rising edge of PCLK250. All signals that are defined to have an asserted state are considered positive-active; meaning that their asserted level is a logical '1'.

# Table 8. TLP Transmit Interface Signal Descriptions

Signal Name	I/О Туре	Timing	Description
TL_TX_REQUEST	Input	Begin	When asserted, indicates an active TLP transmit request. This signal is expected to be driven directly from a latch (which results in reduced latency through the core). TL_TX_REQUEST may be deasserted one cycle after DL_TX_NEXTDATA is initially asserted for the current TLP request. It may also be held asserted to indicate a new request, but such a new request is not recognized until one cycle after the current TLP transmission is completed (TL_TX_COMPLETE asserted and DL_TX_NEXTDATA asserted).
TL_TX_DATA(127:0) TL_TX_DATA(63:0) TL_TX_DATA(31:0)	Input	Middle	Data for the TLP. The least significant byte (bits (7:0)) is transmitted first in the lowest numbered lane of the link and the most significant byte (bits (127:120)) is transmitted last. The core does not distinguish between TLP header and data information, so care must be taken when supplying data on this bus to ensure correct transmission order over the link. See <i>Section 4.5.3, TL_TX_DATA Mapping to PCI Express Link Lanes, on page 36</i> for more information. <b>Note:</b> The width of this signal depends on the configuration of the core. It is (31:0) when the core is configured for a x1 or x4 Physical Link Width, (63:0) when configured for a x8 Physical Link Width, and (127:0) when configured for a x16 Physical Link Width.
TL_TX_DATASIZE(1:0) TL_TX_DATASIZE (Does not exist for x1 or x4)	Input	Middle	<ul> <li>This signal is used to indicate how many of the 32-bit double-words of the TL_TX_DATA data bus have valid data at the end of the packet.</li> <li>Note: The width and existence of this signal depends on the configuration of the core. It does not exist when the core is configured for a x1 or x4 Physical Link Width, it is 1 bit when configured for a x8 Physical Link Width, and (1:0) when configured for a x16 Physical Link Width.</li> <li>The encodings are as follows when configured for a x8 Physical Link Width: '0' indicates that two double-words are valid.</li> <li>'1' indicates that only the double-word in bits (31:0) is valid.</li> <li>The encodings are as follows when configured for a x16 Physical Link Width: '00' indicates that only the double-word in bits (31:0) is valid.</li> <li>The encodings are as follows when configured for a x16 Physical Link Width: '00' indicates that four double-words are valid.</li> <li>'10' indicates that four double-words in bits (31:0) is valid.</li> <li>'10' indicates that the two double-words in bits (31:0) is valid.</li> <li>'10' indicates that the two double-words in bits (31:0) are valid.</li> <li>'11' indicates that the three double-words in bits (95:0) are valid.</li> </ul>
TL_TX_NULLIFY	Input	Middle	This signal may be asserted when TL_TX_COMPLETE is asserted to cause the TLP to be nullified.
TL_TX_COMPLETE	Input	Middle	This signal must be asserted when the data driven on the TL_TX_DATA bus is the last data for the TLP being transmitted.
DL_TX_NEXTDATA	Output	Middle	When asserted, indicates that the core has captured the data on the TL_TX_DATA bus and new data must be presented the following cycle. If asserted when TL_TX_COMPLETE is asserted, it indicates that the TLP transmission has been completed and the core is ready to transmit another TLP. Depending on the negotiated link width and the current traffic flow, DL_TX_NEXTDATA may be asserted in the same cycle that TL_TX_REQUEST is asserted or at any time afterward.

## 4.5.1 TLP Transmit Latency

The best-case TLP transmit latency occurs under the following conditions:

- The link is currently in the L0 link state
- No DLLP transmit requests are currently pending
- No skip-ordered sets are currently pending

If these conditions are true, then three PCLK250 clock cycles will elapse from the time TL\_TX\_REQUEST is asserted to when the STP symbol of the framed TLP is driven on the PHY interface. *Figure 15* shows an example timing diagram. Note that this latency is the same for all negotiated link widths.

## 4.5.2 TLP Transmit Interface Protocol

Transmitting a TLP proceeds according to the following steps. See *Figure 16 on page 34*, *Figure 17 on page 35*, and *Figure 18 on page 35* for example timing diagrams showing operation of this interface when various link widths have been negotiated.

- 1. A new TLP transmit request is signalled by asserting TL\_TX\_REQUEST.
  - TL\_TX\_DATA bus must be driven with the first data of the TLP.
  - If the TLP is three double-words in length, TL\_TX\_COMPLETE must be asserted and TL\_TX\_DATASIZE must be driven to '11' at the same time TL\_TX\_REQUEST is asserted.
  - If the TLP is four double-words in length, TL\_TX\_COMPLETE must be asserted and TL\_TX\_DATASIZE must be driven to '00' at the same time TL\_TX\_REQUEST is asserted.
  - TLPs of one or two double-words are illegal, and if such a transfer is requested by driving TL\_TX\_DATASIZE to '01' or '10' and asserting TL\_TX\_COMPLETE with TL\_TX\_REQUEST, the request will be treated as a three double-word request.
  - When the TLP transmit request is the highest priority (which could be the same cycle TL\_TX\_REQUEST is asserted or an undefined amount of time later), the core initiates a TLP transmit.
- 2. When the data currently driven on the TL\_TX\_DATA bus has been stored by the core, DL\_TX\_NEXTDATA is asserted.
  - TL\_TX\_DATA must be updated with the next data to be transmitted one cycle after DL\_TX\_NEXTDATA is asserted.

- The core continues to transmit data and assert DL\_TX\_NEXTDATA until TL\_TX\_COMPLETE is asserted.
- Note from the example timing diagrams that the number of cycles between assertions of DL\_TX\_NEXTDATA depends on the negotiated link width. It is asserted in consecutive cycles when the negotiated link width is x16. When the negotiated link size is smaller than x16, DL\_TX\_NEXTDATA is asserted less frequently: every two cycles in the case of a x8 link, every 4 cycles in the case of a x4 link, and every 16 cycles in the case of a x1 link. Transaction layer logic should not assume any specific interval between assertions of DL\_TX\_NEXTDATA.
- After the first assertion of DL\_TX\_NEXTDATA for a TLP request, TL\_TX\_REQUEST may be deasserted without affecting the TLP in-progress. TL\_TX\_REQUEST is ignored until one cycle after DL\_TX\_NEXTDATA and TL\_TX\_COMPLETE are asserted.
- 3. When the last data of the TLP is presented on the TL\_TX\_DATA bus, TL\_TX\_COMPLETE must be asserted.
  - At this time, TL\_TX\_DATASIZE must be driven to a value indicating the final number of double-words to be transmitted. TL\_TX\_DATASIZE must not change while TL\_TX\_COMPLETE is asserted. TL\_TX\_DATASIZE only needs to be valid while TL\_TX\_COMPLETE is asserted.
  - Also at this time, TL\_TX\_NULLIFY may be asserted to indicate that the TLP is to be nullified. TL\_TX\_NULLIFY must not change while TL\_TX\_COMPLETE is asserted. TL\_TX\_NULLIFY only needs to be valid while TL\_TX\_COMPLETE is asserted.

## Figure 16. Timing Diagram for TLP Transmit – Negotiated Link Size of x16

#### PCI Express x16 Data Link and Logical Physical

#### Figure 17. Timing Diagram for TLP Transmit – Negotiated Link Sized of x8

*Figure 19* shows the maximum rate of TLP transmission using this interface. The interval between two consecutive TLP transmit requests may be zero cycles (as shown in *Figure 19 on page 36*), but may be extended by many factors including, but not limited to:

- The negotiated link width
- The number of TLPs currently outstanding on the link
- The priority of any DLLPs currently scheduled for transmission
- Skip ordered set insertion

## PCI Express x16 Data Link and Logical Physical

## Figure 19. Timing Diagram for Back-to-Back TLP Transmit – Negotiated Link Size of x16

## 4.5.3 TL\_TX\_DATA Mapping to PCI Express Link Lanes

The data presented to the core on the TL\_TX\_DATA bus is mapped to the PCI Express link such that the least significant byte (bits (7:0)) is transmitted first in the lowest numbered lane of the link and the most significant byte (bits (127:120)) is transmitted last. An example mapping of a TLP to a x16 link is shown graphically in *Figure 20 on page 37*. In the example, the TLP consists of a 3 DWord header and a 1 DWord data payload.

Note that byte +0 of header DWord 0 must be transmitted first, and so the header DWords are byte-reversed when they are mapped to the TL\_TX\_DATA bus (see section 2.1.2 Packet Format Overview in the *PCI Express Base Specification* for more information). Also note that the lowest addressed byte of the data payload must be transmitted first (see section 2.2.2 TLPs with Data Payloads - Rules in the *PCI Express Base Specification* for more information). Data DWords may or may not need to be byte reversed depending on the source of the data and the endianness of the system. The figure shows an example of how a little endian based system might operate - the data DWord is NOT byte-reversed.

## Figure 20. Example Mapping of a 4 DWord TLP on TL\_TX\_DATA to a x16 Link

# 4.5.4 Transmit TLP Length Considerations

As described in *Section 4.5.2, TLP Transmit Interface Protocol*, TLPs must be a minimum of 3 DWords in length and the interface protocol ensures this.

Maximum TLP length, however, is not ensured by the interface protocol. Instead, the transaction layer logic must ensure that TLPs presented to this core for transmission must not exceed the number of 16-byte transfers on the TL\_TX\_DATA bus required to transfer a TLP that contains a 4 DWord header, a payload of the configured maximum payload size supported (see *Section 5.1.2, Replay Buffer Size* for more information), and a TLP digest field. For example, suppose the configured maximum payload size supported is 256 bytes. In this case, a 4 DWord header requires 1 transfer on the TL\_TX\_DATA bus (16 bytes), a maximum size payload requires 16 transfers (256 bytes), and the digest requires 1 additional transfer since the header and payload are both multiples of 16 bytes, for a total of 18 transfers.

If the transaction layer exceeds the maximum number of transfers for a TLP, the behavior of this core is undefined and a reset may be required to return to normal operation. The core does, however, allow for one transfer over the maximum as long as the TLP is nullified.

# 4.6 TLP Receive Interface

The TLP receive interface is used to transfer received TLPs to the transaction layer logic.

**Note:** Some of this interface's signals are affected by the Physical Link Width configuration option. See *Section 5.1.1 Physical Link Width* on page 71 for more information.

All output signals are synchronous to the rising edge of PCLK250. All signals that are defined to have an asserted state are considered positive-active; meaning that their asserted level is a logical '1'.

Figure 21. TLP Receive Interface Signal Diagram

# Table 9. TLP Receive Interface Signal Descriptions (Page 1 of 2)

Signal Name	I/O Type	Timing	Description
DL_RX_DATA(127:0) DL_RX_DATA(63:0) DL_RX_DATA(31:0)	Output	Early	TLP data. The least significant byte (bits (7:0)) contains the data byte which was received first (in the lowest numbered lane of the link) and the most significant byte (bits (127:120)) is the byte received last. The core does not distinguish between TLP header and data information, so care must be taken when decoding this data to ensure proper interpretation of the packet. <b>Note:</b> The width of this signal depends on the configuration of the core. It is (31:0) when the core is configured for a x1 or x4 Physical Link Width, (63:0) when configured for a x8 Physical Link Width, and (127:0) when configured for a x16 Physical Link Width.
DL_RX_DATAVALID	Output	Early	When asserted, this signal indicates that a TLP is being received and the DL_RX_DATA bus must be sampled by the transaction layer logic. The first assertion of this signal, after either a core reset or an assertion of DL_RX_COMPLETE, indicates the start of a TLP.

## Table 9. TLP Receive Interface Signal Descriptions (Page 2 of 2)

Signal Name	I/O Type	Timing	Description
DL_RX_DATASIZE(1:0) DL_RX_DATASIZE (Does not exist for x1 or x4)	Output	Early	This signal is used to indicate how many of the 32-bit double-words of the data bus have valid data at the end of the packet.
			<b>Note:</b> The width and existence of this signal depends on the configuration of the core. It does not exist when the core is configured for a x1 or x4 Physical Link Width, it is 1 bit when configured for a x8 Physical Link Width, and (1:0) when configured for a x16 Physical Link Width.
			The encodings are as follows when configured for a x8 Physical Link Width: '0' indicates that two double-words are valid
			(1) indicates that only the one double-word in hits (31:0) is valid
			This signal is used only when both DL_RX_DATAVALID and DL_RX_COMPLETE are asserted. If only DL_RX_COMPLETE is asserted, all data for the packet was transferred in a previous cycle and the TLP was a multiple of two double-words in length.
			The encodings are as follows when configured for a x8 Physical Link Width: '00' indicates that four double-words are valid.
			'01' indicates that only the one double-word in bits (31:0) is valid.
			'10' indicates that the two double-words in bits (63:0) are valid.
			'11' indicates that the three double-words in bits (95:0) are valid.
			This signal is used only when both DL_RX_DATAVALID and DL_RX_COMPLETE are asserted. If only DL_RX_COMPLETE is asserted, all data for the packet was transferred in a previous cycle and the TLP was a multiple of four double-words in length. This signal will be '01' when DL_RX_SPLITHEADER is asserted.
DL_RX_SPLITHEADER	Output	Early	When asserted, this signal indicates that DL_RX_DATA contains the following information: the last double-word from the TLP in-progress on bits (31:0) and one double-word for the next TLP being received on bits (127:96).
			<b>Note:</b> This signal only exists when the core is configured for a x16 Physical Link Width.
DL_RX_NULLIFY	Output	Middle	When asserted with DL_RX_COMPLETE, this signal indicates that the TLP was nullified by the sender or an error occurred while receiving the TLP. All data for the TLP must be discarded. If this signal is asserted in the same cycle DL_RX_SPLITHEADER is asserted, it indicates that the TLP in-progress (not the new TLP) was nullified.
DL_RX_COMPLETE	Output	Early	This signal is asserted for one cycle when all data for the current TLP has been transferred. This signal may be asserted with DL_RX_DATAVALID, which indicates the last data for the TLP and completion of the TLP, or it may be asserted after DL_RX_DATAVALID is asserted indicating that all data was transferred previously. This signal is asserted for one cycle for each TLP completed, and may be asserted in consecutive cycles. This signal will be asserted if DL_RX_SPLITHEADER is asserted.

#### 4.6.1 TLP Receive Latency

If the link is currently in the L0 link state, five PCLK250 clock cycles will elapse from the time the END or EDB symbol of the framed TLP is received from the PHY interface to when DL\_RX\_COMPLETE is asserted on the TLP Receive interface. *Figure 22* on page 40 shows an example timing diagram. Note that this latency is the same for all negotiated link widths.

PCLK250	
Data from PHY	······· Packet header and payload ) END
DL_RX_COMPLETE	
	Five Cycle Latency

## 4.6.2 TLP Receive Interface Protocol

The TLP receive interface is active only when DL\_LINKUP is asserted. See *Figure 23 on page 41*, *Figure 24 on page 41*, *Figure 25 on page 41*, *Figure 26 on page 42*, and *Figure 27 on page 42* for example timing diagrams showing the operation of this interface when various link widths have been negotiated.

Operation of this interface is as follows:

- 1. The core drives DL\_RX\_DATA and asserts DL\_RX\_DATAVALID for one clock cycle to indicate data was received by the link.
- 2. The end of a TLP and the last data for the TLP may be signalled in three different ways depending on the negotiated link size and the alignment of the traffic on the link.
  - Scenario A: The core drives DL\_RX\_DATA and asserts DL\_RX\_DATAVALID, and at the same time asserts DL\_RX\_COMPLETE and drives DL\_RX\_DATASIZE to indicate the number of double-words valid at the end of the TLP. An example of this scenario is shown in *Figure 23 on page 41*.
  - Scenario B: The core drives DL\_RX\_DATA and asserts DL\_RX\_DATAVALID. Then, at least one cycle later, it asserts DL\_RX\_COMPLETE *without* asserting DL\_RX\_DATAVALID. This indicates that the TLP's length was a multiple of four double-words and that all data was transferred with the previous assertion of DL\_RX\_DATAVALID. No data is transferred in this case and DL\_RX\_DATASIZE must be ignored. Examples of this scenario are shown in *Figure 24 on page 41*, *Figure 25 on page 41*, and *Figure 26 on page 42*.
  - Scenario C: The core drives DL\_RX\_DATA, asserts DL\_RX\_DATAVALID, DL\_RX\_SPLITHEADER, DL\_RX\_COMPLETE, and drives DL\_RX\_DATASIZE to '01'. This indicates the completion of one TLP and the start of another TLP. Bits (31:0) of DL\_RX\_DATA are the last double-word of the current TLP and bits (127:96) of DL\_RX\_DATA are the first double-word of the next TLP. An example of this scenario is shown in *Figure 27 on page 42*.
  - Note that DL\_RX\_COMPLETE may be asserted the first time DL\_RX\_DATAVALID is asserted for a
    packet. This can occur when the TLP is four double-words or less in length. One and two double-word
    TLPs are considered malformed according to the PCI Express Base Specification: they may be
    passed to the transaction layer, so transaction layer logic should check for this condition.
  - Note that DL\_RX\_NULLIFY may be asserted when DL\_RX\_COMPLETE is asserted (in any of the three scenarios described above) to indicate that the packet should be discarded with no further action.

# Figure 23. Timing Diagram for TLP Receive – Negotiated Link Size of x16 and DL\_RX\_COMPLETE Asserted with DL\_RX\_DATAVALID

# Figure 24. Timing Diagram for TLP Receive – Negotiated Link Size of x16 and DL\_RX\_COMPLETE Asserted after DL\_RX\_DATAVALID

# Figure 25. Timing Diagram for TLP Receive – Negotiated Link Size of x8 and DL\_RX\_COMPLETE Asserted after DL\_RX\_DATAVALID

# 4.6.3 PCI Express Link Lane Mapping to DL\_RX\_DATA

The data received by the core on the PCI Express link is mapped to the DL\_RX\_DATA bus such that the byte received on the lowest numbered lane of the link is mapped to the least significant byte (bits (7:0)). This is exactly the reverse of how the core transmits data, see *Section 4.5.3, TL\_TX\_DATA Mapping to PCI Express Link Lanes, on page 36* for more information. An example mapping of a TLP received on a x16 link is shown graphically in *Figure 28 on page 43*. In the example, the TLP consists of a 3 DWord header and a 1 DWord data payload.

Note that byte +0 of header DWord 0 is received first, and so bits (31:0) of DL\_RX\_DATA are byte-reversed header DWord 0. The data payload is mapped in the same manner, however, the data may or may not need to be byte-reversed depending on the source of the data and the endianness of the system.

#### Figure 28. Example Mapping of a 4 DWord TLP Received on a x16 Link to DL\_RX\_DATA

# 4.7 Flow Control Interface

The flow control interface is used to transmit flow control information for the local component and to receive flow control information from the remote component. The interface consists of three sub-interfaces: initialization transmit, update transmit, and flow control receive.

All input signals must be synchronous to the rising edge of PCLK250. All output signals are synchronous to the rising edge of PCLK250. All signals which are defined to have an asserted state are considered positive-active; meaning that their asserted level is a logical '1'.

# Table 10. Flow Control Interface Signal Descriptions (Page 1 of 2)

Signal Name	I/O Type	Timing	Description
TL_FCI_VCNUMBER(2:0)	Input	Middle	Used for flow control initialization. The number of the VC to be initialized.
TL_FCI_PCREDIT(19:0)	Input	Middle	Used for flow control initialization. Posted request credit information for the VC to be initialized. Bits (11:0) are the data credit information. Bits (19:12) are the header credit information.
TL_FCI_NPCREDIT(19:0)	Input	Middle	Used for flow control initialization. Non-posted request credit information for the VC to be initialized. Bits (11:0) are the data credit information. Bits (19:12) are the header credit information.
TL_FCI_CPLCREDIT(19:0)	Input	Middle	Used for flow control initialization. Completion credit information for the VC to be initialized. Bits (11:0) are the data credit information. Bits (19:12) are the header credit information.
TL_FCI_INITFC1	Input	Middle	Used for flow control initialization. When asserted, the TL_FCI_INITFC1 signal causes the DL to send InitFC1 DLLPs for the VC specified by TL_FCI_VCNUMBER. When de-asserted, this signal must not be asserted when DL_FCI_BUSY is asserted.
TL_FCI_INITFC2	Input	Middle	Used for flow control initialization. When asserted, the TL_FCI_INITFC2 signal causes the DL to send InitFC2 DLLPs for the VC specified by TL_FCI_VCNUMBER. When de-asserted, this signal must not be asserted when DL_FCI_BUSY is asserted.

## PCI Express x16 Data Link and Logical Physical

# Table 10. Flow Control Interface Signal Descriptions (Page 2 of 2)

Signal Name	I/О Туре	Timing	Description
DL_FCI_BUSY	Output	Begin	Used for flow control initialization. Asserted when InitFC1 or InitFC2 DLLPs are being transmitted.
TL_FCU_VCNUMBER(2:0)	Input	Middle	Used to transmit flow control updates. The number of the VC to be updated.
TL_FCU_CREDITTYPE(1:0)	Input	Middle	Used to transmit flow control updates. The credit type of the update request. The encodings are: '00' = Posted '01' = Non-posted '10' = Completion The '11' type is reserved. If it is used, the request will be consumed by the core and no DLLP is transmitted.
TL_FCU_CREDIT(19:0)	Input	Middle	Used to transmit flow control updates. The credit information. Bits (11:0) are the data credit information. Bits (19:12) are the header credit information.
TL_FCU_UPDATE	Input	Middle	Used to transmit flow control updates. When asserted, the TL_FCU_UPDATE signal causes an UpdateFC DLLP to be transmitted for the VC specified by TL_FCU_VCNUMBER.
TL_INFCREDIT	Input	Middle	Used to indicate that the remote component has infinite credits available for all enabled VC types. Note: See <i>Section 4.7.1, Use of the TL_INFCREDIT Input, on page 46</i> for more information.
DL_FCU_COMPLETE	Output	Early	Used to transmit flow control updates. Asserted for one cycle when an UpdateFC DLLP for the current TL_FCU_UPDATE request has been queued for transmission.
DL_FCR_INITFC1	Output	Early	Used to receive flow control updates. When asserted, this signal indicates that an InitFC1 DLLP was received with the information described by the DL_FCR_VCNUMBER, DL_FCR_CREDITTYPE, and DL_FCR_CREDIT sig- nals. This signal is asserted for one cycle for each DLLP of this type received. Only one of DL_FCR_INITFC1, DL_FCR_INITFC2, and DL_FCR_UPDATE is asserted in any one cycle, but any combination of the three may occur in back-to- back cycles.
DL_FCR_INITFC2	Output	Early	Used to receive flow control updates. When asserted, this signal indicates that an InitFC2 DLLP was received with the information described by the DL_FCR_VCNUMBER, DL_FCR_CREDITTYPE, and DL_FCR_CREDIT signals. This signal is asserted for one cycle for each DLLP of this type received.
DL_FCR_UPDATE	Output	Early	Used to receive flow control updates. When asserted, this signal indicates that an UpdateFC DLLP was received with the information described by the DL_FCR_VCNUMBER, DL_FCR_CREDITTYPE, and DL_FCR_CREDIT signals. This signal is asserted for one cycle for each DLLP of this type received.
DL_FCR_VCNUMBER(2:0)	Output	Early	Used to receive flow control updates. The VC number of the received flow control DLLP.
DL_FCR_CREDITTYPE(1:0)	Output	Early	Used to receive flow control updates. The credit type of the received DLLP. The encodings are: '00' = Posted '01' = Non-posted '10' = Completion An encoding of '11' will <i>not</i> be driven on this interface.
DL_FCK_CKEDII(19:0)	Output	Early	credit information. Bits (19:12) are the header credit information.

# 4.7.1 Use of the TL\_INFCREDIT Input

The *PCI Express Base Specification* defines a timer that tracks when the last flow control update was received from the remote component. Normally, flow control information is updated every 30  $\mu$ s, so if the timer reaches 200  $\mu$ s, it is assumed that flow control updates have been lost and the link is retrained. However, if a credit type has been initialized with infinite credit, then no flow control updates are required. TL\_INFCREDIT should be asserted if all types for all enabled virtual channels have been initialized with infinite credit from the remote component to prevent the timer from timing out and retraining the link when no retrain is necessary.

# 4.7.2 Initializing Flow Control for a Virtual Channel

The initialization sub-interface may be used only when DL\_LINKUP is asserted. If DL\_LINKUP is deasserted during a flow control initialization sequence, TL\_FCI\_INITFC1, and TL\_FCI\_INITFC2 must be deasserted within one clock cycle and the initialization that was in progress is considered cancelled.

A flow control initialization proceeds as follows (see Figure 30 on page 47):

- 1. TL\_FCI\_VCNUMBER, TL\_FCI\_PCREDIT, TL\_FCI\_NPCREDIT, and TL\_FCI\_CPLCREDIT are driven to the desired values and TL\_FCI\_INITFC1 is asserted.
  - The transaction layer logic must ensure that DL\_FCI\_BUSY is deasserted before asserting TL\_FCI\_INITFC1.
  - The assertion of TL\_FCI\_INITFC1 causes the core to sample the VC number and credit information and begin to transmit InitFC1 DLLPs with the information supplied. The DLLPs are transmitted repeatedly and are guaranteed to be transmitted at an interval less than 34 μs. If the link is in the L0s power management state, it will be returned to the L0 state and then the DLLPs will be transmitted. If the link is in the L1 power management state, transaction layer logic must return the link to the L0 state in order for DLLPs to be transmitted.
  - Transaction layer logic must monitor the flow control receive interface to look for flow control initialization information from the remote component. TL\_FCI\_INITFC1 must be held asserted until Flag FI1 is set, as described in the *PCI Express Base Specification*.
  - The core will assert DL\_FCI\_BUSY one cycle after TL\_FCI\_INITFC1 is asserted to indicate to the transaction layer logic that the flow control initialization request is active. The VC number and credit information may be changed once DL\_FCI\_BUSY is asserted.
- 2. TL\_FCI\_INITFC1 is deasserted and TL\_FCI\_INITFC2 is asserted.
  - This causes the core to switch to transmitting InitFC2 DLLPs with the credit and VC information sampled in step 1. The DLLPs are transmitted repeatedly and are guaranteed to be transmitted at an interval less than 34  $\mu$ s. If the link is in the L0s power management state, it will be returned to the L0 state and then the DLLPs will be transmitted. If the link is in the L1 power management state, transaction layer logic must return the link to the L0 state in order for DLLPs to be transmitted.
  - Transaction layer logic must monitor the flow control receive interface to look for flow control initialization information from the remote component. TL\_FCI\_INITFC2 must be held asserted until Flag Fl2 is set, as described in the *PCI Express Base Specification*.
- 3. TL\_FCI\_INITFC2 is deasserted.
  - The core will complete the current DLLP transmission (either InitFC1 or InitFC2) and deassert DL\_FCI\_BUSY. There may be a significant delay between the deassertion of TL\_FCI\_INITFC2 and the deassertion of DL\_FCI\_BUSY.

#### PCI Express x16 Data Link and Logical Physical

• The transaction layer logic must wait for DL\_FCI\_BUSY to be deasserted before attempting to initialize another virtual channel.

**Note:** When flow control initialization is in-progress for any virtual channel, software should not initiate any device power state changes in either component of the link that would initiate an L1 or L2/3 link condition. In addition, Active State Power Management L1 should not be enabled during flow control initialization. Low power link states will significantly increase the time required to initialize flow control.

# 4.7.3 Transmitting Flow Control Update Information

The update transmit sub-interface may be used only when DL\_LINKUP is asserted. If DL\_LINKUP is deasserted during a flow control update request, TL\_FCU\_UPDATE must be deasserted within one clock cycle and the initialization that was in progress is considered cancelled.

A flow control update proceeds as follows (refer to Figure 31):

- 1. TL\_FCU\_VCNUMBER, TL\_FCU\_CREDITTYPE, and TL\_FCU\_CREDIT are driven to the desired values and TL\_FCU\_UPDATE is asserted.
  - TL\_FCU\_VCNUMBER, TL\_FCU\_CREDITTYPE, and TL\_FCU\_CREDIT may change while TL\_FCU\_UPDATE is asserted.
  - TL\_FCU\_UPDATE must remain asserted until DL\_FCU\_COMPLETE is asserted.
- 2. Once the request has been recognized, the core asserts DL\_FCU\_COMPLETE for one cycle.
  - TL\_FCU\_VCNUMBER, TL\_FCU\_CREDITTYPE, and TL\_FCU\_CREDIT are sampled when DL\_FCU\_COMPLETE is asserted and those values are used to transmit the update to the remote component.

- If the transaction layer logic wants to drive another flow control update, TL\_FCU\_UPDATE may be held asserted and TL\_FCU\_VCNUMBER, TL\_FCU\_CREDITTYPE, and TL\_FCU\_CREDIT are driven to new values the cycle after DL\_FCU\_COMPLETE is asserted.
- If the transaction layer logic does not want to transmit another flow control update, TL\_FCU\_UPDATE should be deasserted in the cycle following the assertion of DL\_FCU\_COMPLETE.

Figure 31. Timing Diagram for Transmitted Flow Control Updates

# 4.7.4 Receiving Flow Control Information

The receive sub-interface is only active when DL\_LINKUP is asserted.

The reception of a valid flow control DLLP is signalled by driving DL\_FCR\_VCNUMBER, DL\_FCR\_CREDITTYPE, and DL\_FCR\_CREDIT to the received values and asserting one of DL\_FCR\_INTFC1, DL\_FCR\_INITFC2, or DL\_FCR\_UPDATE (refer to *Figure 32*). Only one of DL\_FCR\_INITFC1, DL\_FCR\_INITFC2, and DL\_FCR\_UPDATE will be asserted in any one cycle - they are mutually exclusive.

**Note:** Flow control receive information must be handled immediately by transaction layer logic. When a link width of x8 or x16 is negotiated, a flow control DLLP may be received by the core every symbol time, and if so, DL\_FCR\_INITFC1, DL\_FCR\_INITFC2, or DL\_FCR\_UPDATE may be asserted in consecutive cycles. For each cycle a signal is asserted, flow control information must be processed.

#### PCI Express x16 Data Link and Logical Physical

#### Figure 32. Timing Diagram for Received Flow Control

# 4.8 Power Management Interface

The power management interface is used to control and signal entry to and exit from the L0, Active State Power Management L1, PCI Power Management L1, and PCI Power Management L2/L3 Ready link states.

All input signals must be synchronous to the rising edge of PCLK250. All output signals are synchronous to the rising edge of PCLK250. All signals which are defined to have an asserted state are considered positive-active; meaning that their asserted level is a logical '1'.

Table 11. Fuwel Management Internace Signal Descriptions	Table 11	. Power Managemen	t Interface Signal	Descriptions
--	----------	-------------------	--------------------	--------------

Signal Name	I/O Type	Timing	Description
TL_PM_GOTOL0	Input	Middle	This signal should be asserted for one PCLK250 cycle to initiate the desired action. When asserted in an upstream facing port configuration, this signal cancels a pending active state L1 request or initiates an exit from the L1 state. When asserted in a downstream facing port configuration, this signal initiates an exit from the L1 state.
TL_PM_GOTOL1	Input	Middle	This signal should be asserted for one PCLK250 cycle to initiate the desired action. When asserted in an upstream facing port configuration, this signal initiates the L1 protocol. When asserted in a downstream facing port configuration, this signal acknowledges an L1 request. Note: The transaction layer must not attempt to transmit a TLP after asserting this signal and until the L1 state has been entered and subsequently exited.
TL_PM_GOTOACTIVEL1	Input	Middle	This signal should be asserted for one PCLK250 cycle to initiate the desired action. When asserted in an upstream facing port configuration, this signal initiates the active state L1 protocol. This signal is not used in a downstream facing port configuration and may be set to any value. Note: The transaction layer must not attempt to transmit a TLP after asserting this signal and until the L1 state has been entered and subsequently exited or until the active state L1 request is cancelled by an assertion of TL_PM_GOTOL0.
TL_PM_GOTOL23	Input	Middle	This signal should be asserted for one PCLK250 cycle to initiate the desired action. When asserted in an upstream facing port configuration, this signal initiates the L23 protocol. When asserted in a downstream facing port configuration, this signal acknowledges an L23 request. Note: The transaction layer must not attempt to transmit a TLP after asserting this signal.
DL_PM_ENTERL1	Output	Early	This signal is asserted for one PCLK250 clock cycle when the core is in a down- stream facing port configuration and a PM_Enter_L1 DLLP is received.
DL_PM_ACTIVEL1	Output	Early	This signal is asserted for one PCLK250 clock cycle when the core is in a down- stream facing port configuration and a PM_Active_State_Request_L1 DLLP is received.
DL_PM_ENTERL23	Output	Early	This signal is asserted for one PCLK250 clock cycle when the core is in a down- stream facing port configuration and a PM_Enter_L23 DLLP is received.
DL_PM_INL1	Output	Early	This signal is asserted when the link is in the L1 state (whether due to an active state L1 request or a standard L1 request). It is asserted in both downstream and upstream facing port configurations. Note: The transaction layer must not attempt to transmit a TLP when this signal is asserted.
DL_PM_INL23	Output	Early	This signal is asserted when the link is in the L2/L3 ready state. It is asserted in both downstream and upstream facing port configurations. Note: The transaction layer must not attempt to transmit a TLP when this signal is asserted.

#### 4.8.1 Active State Power Management – L0s Link State

This interface is *not* used to control entry to and exit from the L0s link state. The transmitter enters L0s automatically when L0s is enabled in the link control register and no DLLP or TLP requests have been made for the number of symbol times (PCLK250 clock cycles) for which the core has been configured (see *Section 5.1.4, L0s Entry Timeout Setting, on page 73* for more information). The transmitter exits L0s automatically when a DLLP or TLP request is made. The receiver enters and exits L0s automatically based on the state of the link.

#### 4.8.2 Active State Power Management – L1 Link State

The core supports the ASPM L1 link state as both an upstream and downstream facing port. Upstream facing ports may request this link state, and downstream facing ports may accept or reject the request.

#### 4.8.2.1 ASPM L1 for an Upstream Facing Port

When an upstream facing port requests the ASPM L1 link state and the request is accepted, the sequence of events is as follows (see *Figure 34 on page 51* for an example timing diagram):

- The transaction layer logic asserts TL\_PM\_GOTOACTIVEL1 for one cycle.
  - This causes PM\_Active\_State\_Request\_L1 DLLPs to be transmitted upstream.
- This core receives at least one PM\_Request\_Ack DLLP from upstream.
  - The remaining stages of the protocol are completed by this core automatically.
- DL\_PM\_INL1 is asserted when the link is in the ASPM L1 link state.

# Figure 34. ASPM L1 Transition – Upstream Facing Port

When an upstream facing port requests the ASPM L1 link state and the request is rejected, the sequence of events is as follows (see *Figure 35 on page 52* for an example timing diagram):

- The transaction layer logic asserts TL\_PM\_GOTOACTIVEL1 for one cycle.
  - This causes PM\_Active\_State\_Request\_L1 DLLPs to be transmitted upstream.
- This core does not receive any PM\_Request\_Ack DLLPs from upstream, but will receive and pass on to the transaction layer a PM\_Active\_State\_Nak TLP.

- The transaction layer logic asserts DL\_PM\_GOTOL0 for one cycle to cancel the ASPM L1 request.
  - This core then stops transmitting PM\_Active\_State\_Request\_L1 DLLPs upstream and the link remains in the L0 link state.
  - A subsequent ASPM L1 request may be initiated one cycle after TL\_PM\_GOTOL0 is asserted. However, the core contains a timer that ensures that at least 11 μs of time will pass before such a request will initiate PM\_Active\_State\_Request\_L1 DLLPs on the link again. This ensures that the upstream component can identify when one ASPM L1 request ends and another begins.

# Figure 35. ASPM L1 Rejection – Upstream Facing Port

# 4.8.2.2 ASPM L1 for a Downstream Facing Port

When a downstream facing port receives an ASPM L1 link state request and accepts it, the sequence of events is as follows (see *Figure 36* for an example timing diagram):

- This core receives at least one PM\_Active\_State\_Request\_L1 DLLP from downstream.
  - DL\_PM\_ACTIVEL1 is asserted for one cycle for the first PM\_Active\_State\_Request\_L1 DLLP received. Subsequent PM\_Active\_State\_Request\_L1 DLLPs do not cause an assertion of DL\_PM\_ACTIVEL1 until the current request ends. The end of the current request is defined as either Link state L0s on the RX side of the link; or 9.5 µs of time while in the L0 link state (time spent in the Recovery state does not count toward the 9.5 µs) during which no PM\_Active\_State\_Request\_L1 DLLPs are received.
- The transaction layer logic asserts TL\_PM\_GOTOL1 for one cycle.
  - This core transmits PM\_Request\_Ack DLLPs downstream and completes the remaining stages of the protocol automatically.
- DL\_PM\_INL1 is asserted when the link is in the ASPM L1 link state.

#### Figure 36. ASPM L1 Transition – Downstream Facing Port

When an downstream facing port receives an ASPM L1 link state request and rejects it, the sequence of events is as follows (see *Figure 37* for an example timing diagram):

- This core receives at least one PM\_Active\_State\_Request\_L1 DLLP from downstream.
  - DL\_PM\_ACTIVEL1 is asserted for one cycle for each PM\_Active\_State\_Request\_L1 DLLP received.
- The transaction layer logic transmits a PM\_Active\_State\_Nak TLP downstream.
  - Once the downstream component receives the TLP, the ASPM L1 request is cancelled and no further action is necessary.

Figure 37. ASPM L1 Rejection – Downstream Facing Port

#### 4.8.2.3 Exiting the ASPM L1 Link State

The ASPM L1 link state may be exited as follows:

- The transaction layer asserts TL\_PM\_GOTOL0 for one cycle.
  - While the link is being recovered, DL\_PM\_INL1 will be deasserted.
- A receive lane detects a non-electrical idle condition on the link (RXELECIDLE is de-asserted).
  - While the link is being recovered, DL\_PM\_INL1 will be deasserted.
- When configured as a downstream facing port and SYS\_TCTX\_DISABLE is asserted.
  - While the link is being recovered, DL\_PM\_INL1 will be deasserted. The link will then proceed to the Disabled state.
- When configured as a downstream facing port and SYS\_TCTX\_RESET is asserted.
  - While the link is being recovered, DL\_PM\_INL1 will be deasserted. The link will then proceed to the Reset state.

# 4.8.3 PCI Power Management – L1 Link State

The core supports the PCI-PM L1 link state as both an upstream and downstream facing port. Upstream facing ports initiate this link state, and downstream facing ports must complete the protocol.

# 4.8.3.1 PCI-PM L1 for an Upstream Facing Port

When an upstream facing port initiates the PCI-PM L1 link state, the sequence of events is as follows (see *Figure 38 on page 54* for an example timing diagram):

- The transaction layer logic asserts TL\_PM\_GOTOL1 for one cycle.
  - This causes PM\_Enter\_L1 DLLPs to be transmitted upstream.
- This core receives at least one PM\_Request\_Ack DLLP from upstream.
  - The remaining stages of the protocol are completed by this core automatically.
- DL\_PM\_INL1 is asserted when the link is in the PCI-PM L1 link state.

# Figure 38. PCI-PM L1 Transition – Upstream Facing Port

## 4.8.3.2 PCI-PM L1 for a Downstream Facing Port

When a downstream facing port receives a PCI-PM L1 link state request, the sequence of events is as follows (see *Figure 39* for an example timing diagram):

- This core receives at least one PM\_Enter\_L1 DLLP from downstream.
  - DL\_PM\_ENTERL1 is asserted for one cycle for each PM\_Enter\_L1 DLLP received.
- The transaction layer logic asserts TL\_PM\_GOTOL1 for one cycle.
  - This core transmits PM\_Request\_Ack DLLPs downstream and completes the remaining stages of the protocol automatically.
- DL\_PM\_INL1 is asserted when the link is in the PCI-PM L1 link state.

## Figure 39. PCI-PM L1 Transition – Downstream Facing Port

#### 4.8.3.3 Exiting the PCI-PM L1 Link State

The PCI-PM L1 link state may be exited by upstream and downstream facing ports as follows (see *Figure 40 on page 56* for an example timing diagram):

- The transaction layer asserts TL\_PM\_GOTOL0 for one cycle.
  - While the link is being recovered, DL\_PM\_INL1 will be deasserted.
- A receive lane detects a non-electrical idle condition on the link (RXELECIDLE is de-asserted).
   While the link is being recovered, DL\_PM\_INL1 will be deasserted.
- When configured as a downstream facing port and SYS\_TCTX\_DISABLE is asserted.
  - While the link is being recovered, DL\_PM\_INL1 will be deasserted. The link will then proceed to the Disabled state.
- When configured as a downstream facing port and SYS\_TCTX\_RESET is asserted.
  - While the link is being recovered, DL\_PM\_INL1 will be deasserted. The link will then proceed to the Reset state.

#### Figure 40. PCI-PM L1 Exit Transition – Upstream and Downstream Facing Port

# 4.8.4 PCI Power Management – L2/L3 Ready Link State

The core supports the PCI-PM L2/L3 ready link state as both an upstream and downstream facing port. Upstream facing ports initiate this link state, and downstream facing ports must complete the protocol.

## 4.8.4.1 PCI-PM L2/L3 Ready for an Upstream Facing Port

When an upstream facing port initiates the PCI-PM L2/L3 ready link state, the sequence of events is as follows (see *Figure 41 on page 57* for an example timing diagram):

- The transaction layer logic asserts TL\_PM\_GOTOL23 for one cycle.
  - This causes PM\_Enter\_L23 DLLPs to be transmitted upstream.
- This core receives at least one PM\_Request\_Ack DLLP from upstream.
  - The remaining stages of the protocol are completed by this core automatically.
- DL\_PM\_INL23 is asserted when the link is in the PCI-PM L2/L3 ready link state.

#### Figure 41. PCI-PM L2/L3 Ready Transition – Upstream Facing Port

#### 4.8.4.2 PCI-PM L2/L3 for a Downstream Facing Port

When a downstream facing port receives a PCI-PM L2/L3 ready link state request, the sequence of events is as follows (see *Figure 42* for an example timing diagram):

- This core receives at least one PM\_Enter\_L23 DLLP from downstream.
  - DL\_PM\_ENTERL23 is asserted for one cycle for each PM\_Enter\_L23 DLLP received.
- The transaction layer logic asserts TL\_PM\_GOTOL23 for one cycle.
  - This core transmits PM\_Request\_Ack DLLPs downstream and completes the remaining stages of the protocol automatically.
- DL\_PM\_INL23 is asserted when the link is in the PCI-PM L2/L3 ready link state.

#### Figure 42. PCI-PM L2/L3 Ready Transition – Downstream Facing Port

# 4.8.4.3 Exiting the PCI-PM L2/L3 Ready Link State

The PCI-PM L2/L3 ready link state can only be exited by asserting SYS\_RESETN. This is due to the fact that the attached PHY has been directed to its P2 power state in which PCLK250 is stopped.

# 4.8.4.4 Use of the DL\_PM\_INL23 Signal and Clocking Issues

The DL\_PM\_INL23 signal is asserted when the link is in the L2/L3 ready link state and the PHY has been directed to its P2 power state. Note that assertion of DL\_PM\_INL23 *does not* guarantee that the PHY is ready for removal of its reference clock. See the *PHY Interface for PCI Express Architecture* specification and the PHY's databook for more information on how and when the PHY will indicate that its reference clock may be stopped.

# 4.9 PHY Interface

The PHY interface of the core complies with the industry standard *PHY Interface for PCI Express Architecture* (PIPE) specification, version 1.00. The core may not operate correctly with PHYs designed to other versions of the PIPE specification.

For more information on the definition, behavior, and usage of each PHY interface signal, refer to the PHY *Interface for PCI Express Architecture* specification.

**Note:** Some of this interface's signals are affected by the Physical Link Width configuration option. See *Section 5.1.1 Physical Link Width* on page 71 for more information.

All signals, except as noted, are synchronous to the rising edge of PCLK250. All signals which are defined to have an asserted state are considered positive-active, meaning that their asserted level is a logical '1'.

## PCI Express x16 Data Link and Logical Physical

# Table 12. PHY Interface Signal Descriptions (Page 2 of 5)

Signal Name	I/О Туре	Timing	Description
RXDATA_15(7:0)	Input	Middle	Data received on the link's physical lane 15. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
RXDATAK(15:0)	Input	Middle	The K-code indicator bit for each lane's RXDATA. Bit 0 corresponds to lane 0 and bit 15 corresponds to lane 15. <b>Note:</b> This signal is one bit when the core is configured for a x1 Physical Link Width, (3:0) when the core is configured for a x4 Physical Link Width, (7:0) when the core is configured for a x8 Physical Link Width, and (15:0) when the core is configured for a x16 Physical Link Width.
RXELECIDLE(15:0)	Input	Async	The Electrical Idle indicator bit for each lane. Bit 0 corresponds to lane 0 and bit 15 corresponds to lane 15. <b>Note:</b> This signal is one bit when the core is configured for a x1 Physical Link Width, (3:0) when the core is configured for a x4 Physical Link Width, (7:0) when the core is configured for a x8 Physical Link Width, and (15:0) when the core is configured for a x16 Physical Link Width.
RXSTATUS_00(2:0)	Input	Middle	Receiver status indicator for lane 0.
RXSTATUS_01(2:0)	Input	Middle	Receiver status indicator for lane 1. <b>Note:</b> This port does not exist when the core is configured for a x1 Physical Link Width.
RXSTATUS_02(2:0)	Input	Middle	Receiver status indicator for lane 2. <b>Note:</b> This port does not exist when the core is configured for a x1 Physical Link Width.
RXSTATUS_03(2:0)	Input	Middle	Receiver status indicator for lane 3. <b>Note:</b> This port does not exist when the core is configured for a x1 Physical Link Width.
RXSTATUS_04(2:0)	Input	Middle	Receiver status indicator for lane 4. <b>Note:</b> This port does not exist when the core is configured for a x1 or x4 Physical Link Width.
RXSTATUS_05(2:0)	Input	Middle	Receiver status indicator for lane 5. <b>Note:</b> This port does not exist when the core is configured for a x1 or x4 Physical Link Width.
RXSTATUS_06(2:0)	Input	Middle	Receiver status indicator for lane 6. <b>Note:</b> This port does not exist when the core is configured for a x1 or x4 Physical Link Width.
RXSTATUS_07(2:0)	Input	Middle	Receiver status indicator for lane 7. <b>Note:</b> This port does not exist when the core is configured for a x1 or x4 Physical Link Width.
RXSTATUS_08(2:0)	Input	Middle	Receiver status indicator for lane 8. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
RXSTATUS_09(2:0)	Input	Middle	Receiver status indicator for lane 9. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
RXSTATUS_10(2:0)	Input	Middle	Receiver status indicator for lane 10. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
RXSTATUS_11(2:0)	Input	Middle	Receiver status indicator for lane 11. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.

# Table 12. PHY Interface Signal Descriptions (Page 3 of 5)

Signal Name	I/O Type	Timing	Description
RXSTATUS_12(2:0)	Input	Middle	Receiver status indicator for lane 12. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
RXSTATUS_13(2:0)	Input	Middle	Receiver status indicator for lane 13. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
RXSTATUS_14(2:0)	Input	Middle	Receiver status indicator for lane 14. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
RXSTATUS_15(2:0)	Input	Middle	Receiver status indicator for lane 15. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
RXVALID(15:0)	Input	Middle	The data valid indicator for each lane's RXDATA. Bit 0 corresponds to lane 0 and bit 15 corresponds to lane 15.
			<b>Note:</b> This signal is one bit when the core is configured for a x1 Physical Link Width, $(3:0)$ when the core is configured for a x4 Physical Link Width, $(7:0)$ when the core is configured for a x8 Physical Link Width, and $(15:0)$ when the core is configured for a x16 Physical Link Width.
POWERDOWN(1:0)	Output	Early	<ul> <li>The power state of the PHY. The encodings are as follows:</li> <li>'00' = P0, normal operation.</li> <li>'01' = P0s, low power state, not transmitting, receive may be active.</li> <li>'10' = P1, low power state, not transmitting or receiving.</li> <li>'11' = P2, lowest power state, all clocks and PLL shut down.</li> </ul>
RXPOLARITY(15:0)	Output	Early	Controls receiver polarity reversal for each lane's RXDATA. Bit 0 corresponds to lane 0 and bit 15 corresponds to lane 15. <b>Note:</b> This signal is one bit when the core is configured for a x1 Physical Link Width, (3:0) when the core is configured for a x4 Physical Link Width, (7:0) when the core is configured for a x8 Physical Link Width, and (15:0) when the core is configured for a x16 Physical Link Width.
TXCOMPLIANCE(15:0)	Output	Early	Controls transmitter encoding disparity of each lane's TXDATA. Bit 0 corresponds to lane 0 and bit 15 corresponds to lane 15. <b>Note:</b> This signal is one bit when the core is configured for a x1 Physical Link Width, (3:0) when the core is configured for a x4 Physical Link Width, (7:0) when the core is configured for a x8 Physical Link Width, and (15:0) when the core is configured for a x16 Physical Link Width.
TXDATA_00(7:0)	Output	Early	Transmit data for the link's physical lane 0.
TXDATA_01(7:0)	Output	Early	Transmit data for the link's physical lane 1. <b>Note:</b> This port does not exist when the core is configured for a x1 Physical Link Width.
TXDATA_02(7:0)	Output	Early	Transmit data for the link's physical lane 2. <b>Note:</b> This port does not exist when the core is configured for a x1 Physical Link Width.
TXDATA_03(7:0)	Output	Early	Transmit data for the link's physical lane 3. <b>Note:</b> This port does not exist when the core is configured for a x1 Physical Link Width.

## PCI Express x16 Data Link and Logical Physical

# Table 12. PHY Interface Signal Descriptions (Page 4 of 5)

Signal Name	I/О Туре	Timing	Description
TXDATA_04(7:0)	Output	Early	Transmit data for the link's physical lane 4. <b>Note:</b> This port does not exist when the core is configured for a x1 or x4 Physical Link Width.
TXDATA_05(7:0)	Output	Early	Transmit data for the link's physical lane 5. <b>Note:</b> This port does not exist when the core is configured for a x1 or x4 Physical Link Width.
TXDATA_06(7:0)	Output	Early	Transmit data for the link's physical lane 6. <b>Note:</b> This port does not exist when the core is configured for a x1 or x4 Physical Link Width.
TXDATA_07(7:0)	Output	Early	Transmit data for the link's physical lane 7. <b>Note:</b> This port does not exist when the core is configured for a x1 or x4 Physical Link Width.
TXDATA_08(7:0)	Output	Early	Transmit data for the link's physical lane 8. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
TXDATA_09(7:0)	Output	Early	Transmit data for the link's physical lane 9. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
TXDATA_10(7:0)	Output	Early	Transmit data for the link's physical lane 10. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
TXDATA_11(7:0)	Output	Early	Transmit data for the link's physical lane 11. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
TXDATA_12(7:0)	Output	Early	Transmit data for the link's physical lane 12. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
TXDATA_13(7:0)	Output	Early	Transmit data for the link's physical lane 13. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
TXDATA_14(7:0)	Output	Early	Transmit data for the link's physical lane 14. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
TXDATA_15(7:0)	Output	Early	Transmit data for the link's physical lane 15. <b>Note:</b> This port does not exist when the core is configured for a x1, x4, or x8 Physical Link Width.
TXDATAK(15:0)	Output	Early	K-code indicator bit for each lane's TXDATA. Bit 0 corresponds to lane 0 and bit 15 corresponds to lane 15. <b>Note:</b> This signal is one bit when the core is configured for a x1 Physical Link Width, (3:0) when the core is configured for a x4 Physical Link Width, (7:0) when the core is configured for a x8 Physical Link Width, and (15:0) when the core is configured for a x16 Physical Link Width.
TXDETECTRX	Output	Early	When asserted, instructs the PHY to execute a receiver detection sequence on all lanes.

#### Table 12. PHY Interface Signal Descriptions (Page 5 of 5)

Signal Name	I/O Type	Timing	Description
TXELECIDLE(15:0)	Output	Early	Electrical idle indicator bit for each lane's transmitter. Bit 0 corresponds to lane 0 and bit 15 corresponds to lane 15. <b>Note:</b> This signal is one bit when the core is configured for a x1 Physical Link Width, (3:0) when the core is configured for a x4 Physical Link Width, (7:0) when the core is configured for a x8 Physical Link Width, and (15:0) when the core is configured for a x16 Physical Link Width.

# 4.9.1 PHY Requirements to Support Exit from the L2/3 Ready Link State

When the core enters the L2/3 Ready link state, it directs the PHY to the P2 power state which is defined to stop the PCLK250 clock from the PHY. However, PCLK250 must be running (not necessarily at 250 MHz) in order for the core to exit from the L2/3 Ready link state. If it is running, then the core exits to the Detect link state if the following conditions occur:

- As an upstream facing port: De-assertion of any RXELECIDLE signal of lanes that are part of the configured link.
- As a downstream facing port: De-assertion of the RXELECIDLE signal corresponding to lane 0 of the configured link, or assertion of SYS\_TCTX\_RESET (see *Section 4.4.1.2 Training Control Reset* on page 30 for more information).

If an exit condition is detected and the state transition is executed, the core directs the PHY to the P1 power state with the POWERDOWN signal. The PHY asserts PHYSTATUS asynchronously when it recognizes the change of POWERDOWN and eventually de-asserts PHYSTATUS synchronously when it completes the power state transition. During this period, the core requires PHYSTATUS to be asserted for at least three rising edges of PCLK250 and PCLK250 must be running at 250 MHz before PHYSTATUS is de-asserted.

# 4.10 TLP Replay Interface

The TLP Replay Interface connects to a synchronous one-port RAM (or equivalent function) and stores TLPs for future replay (if needed) by the link. The RAM must have the following features:

- Synchronous read and write initiated by the rising edge of the clock.
- After a read access takes place, the read data must remain on the RAM outputs until another read access is initiated.
- The RAM's write data input must be connected to TL\_TX\_DATA external to this core.
- The RAM must be clocked with PCLK250—the same clock connected to this core—and therefore must be capable of running at 250 MHz.

**Note:** Some of this interface's signals are affected by the Physical Link Width configuration option. See *Section 5.1.1 Physical Link Width* on page 71 for more information.

**Note:** The replay buffer is described as a single entity, but because it may have a data bus width of 128 bits, multiple RAMs may be needed to create the proper configuration.

All inputs and outputs are synchronous to the rising edge of PCLK250. All signals which are defined to have an asserted state are considered positive-active; meaning that their asserted level is a logical '1'.

# Figure 44. TLP Replay Interface Signal Diagram

# Table 13. TLP Replay Interface Signal Descriptions

Signal Name	I/O Type	Timing	Description
RAM_RDATA(127:0) RAM_RDATA(63:0) RAM_RDATA(31:0)	Input	Late	This is the RAM's read data output. Data read from the RAM must remain stable until another read is initiated. <b>Note:</b> The width of this signal depends on the configuration of the core. It is (31:0) when the core is configured for a x1 or x4 Physical Link Width, (63:0) when configured for a x8 Physical Link Width, and (127:0) when configured for a x16 Physical Link Width.
DL_RAM_ADDR(N:0)	Output	Early	The address to read data from or write data to. The width of this bus is deter- mined by the Max Payload Size Supported configuration option. See <i>Section</i> <i>5.1.2, Replay Buffer Size, on page 71</i> for more information.
DL_RAM_WE	Output	Early	The write enable signal for the RAM.
DL_RAM_CE	Output	Middle	The chip enable signal for the RAM. It is asserted when either a read or a write cycle is initiated. The determination of read versus write is made with the DL_RAM_WE signal.

#### 4.10.1 Writing TLP Data to the Replay Buffer

Data is written to the replay buffer during a transaction layer TLP transmit request. See *Figure 45 on page 66* for an example timing diagram of a write sequence.

- 1. A TLP transmission is requested by asserting TL\_TX\_REQUEST and driving TL\_TX\_DATA with the data to transmit.
- 2. When the core is ready to transmit the TLP, it signals the acceptance of the data by asserting DL\_TX\_NEXTDATA. At same time, it initiates a write to the RAM attached to the TLP Replay interface by driving DL\_RAM\_ADDR and asserting DL\_RAM\_WE and DL\_RAM\_CE.
  - Depending on the negotiated link width and the length of the TLP request, DL\_RAM\_ADDR may change every cycle and DL\_RAM\_WE and DL\_RAM\_CE may be asserted in consecutive cycles. When writing, DL\_RAM\_CE is asserted the same time DL\_TX\_NEXTDATA is asserted on the TLP transmit Interface.

# 4.10.2 Reading TLP Data from a Replay Buffer Configured for One-Cycle Access

Data is read from the replay buffer when a replay is initiated. Refer to *Figure 46 on page 67* for an example timing diagram for a read sequence.

- 1. When a replay is initiated, the core drives DL\_RAM\_ADDR to the starting address of the TLP(s) to be replayed. DL\_RAM\_WE is driven low to indicate a read operation, and DL\_RAM\_CE is asserted for one cycle for each address to be read from.
  - RAM\_DATA must hold its value until a new read is initiated. Depending on the negotiated link width, reads may take place every cycle or may have idle cycles between reads.
- When DL\_RAM\_CE is asserted, a rising edge of PCLK250 initiates a read from the RAM. When configured for a one-cycle read access time, the read must take place and RAM\_RDATA must be valid before the next rising edge of PCLK250.
  - RAM\_RDATA must hold its value until a new read is initiated. Depending on the negotiated link width, reads may take place every cycle or may have idle cycles between reads.

#### 4.10.3 Reading TLP Data from a Replay Buffer Configured for Two-Cycle Access

Data is read from the replay buffer when a replay is initiated. Refer to *Figure 47 on page 67* for an example timing diagram for a read sequence.

- When a replay is initiated, the core drives DL\_RAM\_ADDR to the starting address of the TLP(s) to be replayed. DL\_RAM\_WE is driven low to indicate a read operation, and DL\_RAM\_CE is asserted for one cycle for each address to be read from.
  - RAM\_DATA must hold its value until a new read is initiated. Depending on the negotiated link width, reads may take place every cycle or may have idle cycles between reads.
- When DL\_RAM\_CE is asserted, a rising edge of PCLK250 initiates a read from the RAM. When configured for a two-cycle read access time, the read must take place and RAM\_RDATA must be valid before the second rising edge of PCLK250 after DL\_RAM\_CE is asserted. The RAM must still be capable of producing read data every cycle.
  - RAM\_RDATA must hold its value until a new read is initiated. Depending on the negotiated link width, reads may take place every cycle or may have idle cycles between reads.

## 4.10.4 RAM W/R and R/W Turn-around Time

When switching from write mode (new TLP from the transaction layer) to read mode (replay of previously transmitted TLP), the DL\_RAM\_WE and DL\_RAM\_CE signals are deasserted for at least one PCLK250 cycle before a read is initiated.

When switching from read mode (replay of previously transmitted TLP) to write mode (new TLP from the transaction layer), the DL\_RAM\_CE signal is deasserted for at least one PCLK250 cycle before a write is initiated. The DL\_RAM\_WE signal may be asserted the same cycle DL\_RAM\_CE is asserted to initiate the next write.

# 4.11 Loopback Interface

The loopback interface is active when the core is in master loopback mode. It can be used for link diagnostic purposes. There are two signals per lane: one to indicate whether the lane is in loopback, and one to indicate when an error has been detected. The pattern transmitted by the core is as follows:

- 64 symbols of the compliance pattern (used to provide interference between adjacent lanes)
- One skip-ordered set
- · Repeat until directed to exit loopback mode

The following errors will be detected:

- 8b/10b disparity and decode
- Receiver underflow or overflow
- Unexpected electrical idle at the receiver
- · Loss of symbol lock at the receiver

**Note:** Some of this interface's signals are affected by the Physical Link Width configuration option. See *Section 5.1.1 Physical Link Width* on page 71 for more information.

All inputs and outputs are synchronous to the rising edge of PCLK250. All signals which are defined to have an asserted state are considered positive-active; meaning that their asserted level is a logical '1'.

# Figure 48. Loopback Interface Signal Diagram

#### Table 14. Loopback Interface Signal Descriptions

Signal Name	I/O Type	Timing	Description
DL_LB_ACTIVE(15:0)	Output	Middle	This signal is asserted per lane when the lane is in loopback. <b>Note:</b> This signal is one bit when the core is configured for a x1 Physical Link Width, (3:0) when the core is configured for a x4 Physical Link Width, (7:0) when the core is configured for a x8 Physical Link Width, and (15:0) when the core is configured for a x16 Physical Link Width.
DL_LB_ERROR(15:0)	Output	Middle	This signal is asserted per lane for one PCLK250 cycle each time an error is detected in the received loopback data stream. <b>Note:</b> This signal is one bit when the core is configured for a x1 Physical Link Width, (3:0) when the core is configured for a x4 Physical Link Width, (7:0) when the core is configured for a x8 Physical Link Width, and (15:0) when the core is configured for a x16 Physical Link Width.

# 4.11.1 Entering Master Loopback Mode

See *Section 4.4, Training Control Interface, on page 27* for information on how to direct the core to attempt to enter master loopback mode. Once directed, the following sequence is performed:

- If at least one lane has been determined to be operable, the core enters loopback negotiation which consists of transmitting TS1 ordered sets with the Loopback bit set in the training control field and waiting for them to be looped back. If at least one lane completes loopback negotiation, the core proceeds to checking. DL\_TCRX\_LOOPBACK is asserted at this time.
- 2. The first checking step is to look for a sequence of two bytes on each lane: K28.5 and D21.5. For each lane that receives that sequence without errors, checking is enabled and that lane's DL\_LB\_ACTIVE signal is asserted. From that time on, that lane's DL\_LB\_ERROR is asserted when an error is detected.

The SYS\_TCRX\_LOOPBACK, DL\_LB\_ACTIVE, and DL\_LB\_ERROR signals may be used in the following manner:

- If SYS\_TCRX\_LOOPBACK is asserted, but no DL\_LB\_ACTIVE signals are asserted, this indicates that no lanes have successfully completed loopback negotiation. The link returns to the detect state after a 2 ms timeout.
- If SYS\_TCRX\_LOOPBACK is asserted and at least one DL\_LB\_ACTIVE signal is asserted, this indicates that all lanes for which DL\_LB\_ACTIVE is asserted have completed the loopback negotiation process and are being monitored for errors. DL\_LB\_ERROR is asserted for each of those lanes when an error is detected.
- DL\_LB\_ERROR is not asserted for lanes that have not completed the loopback negotiation process.

# 4.11.2 Exiting Master Loopback Mode

See *Section 4.4, Training Control Interface, on page 27* for information on how to direct the core to exit master loopback mode.

# 4.11.3 Entering Slave Loopback Mode

The core enters slave loopback mode automatically when requested by the remote component.

# 4.11.4 Exiting Slave Loopback Mode

The core exits slave loopback mode automatically when it receives an Electrical Idle ordered set from the remote component.

**Note:** The core continues to direct the attached PHY to loopback incoming data for 19 PCLK250 cycles after receiving the Electrical Idle ordered set. This should allow the PHY sufficient time to loopback the ordered set, but the PHY specification should be checked for compatibility with this behavior.

# 5. Core Integration

# 5.1 Configurability

The core contains five configurable items: the physical link width, the replay buffer size, the replay buffer read access time, the LOs entry timeout value, and use of asynchronously set/reset flip-flops.

Configurability is controlled with the PCIEX16DLP.defines.v file.

# 5.1.1 Physical Link Width

The physical link width supported by the core is controlled with three parameters:

- PCIEXDLP\_LINKWIDTH\_X1
- PCIEXDLP\_LINKWIDTH\_X4
- PCIEXDLP\_LINKWIDTH\_X8
- PCIEXDLP\_LINKWIDTH\_X16

Only one of these parameters may be defined at any one time.

This configuration item is intended to reduce the size of the synthesized core when implementing x1, x4, or x8 PCI Express ports. Note that several signal interfaces on the core are modified depending on the physical link width selected. For example, the TL\_TX\_DATA and DL\_RX\_DATA buses are 32 bits wide when either a x1 or x4 physical link width is chosen. The interface and signal descriptions indicate all signals which are modified with this configuration item.

**Note:** These parameters correspond to the LINKWIDTH parameters which control the link width of the IBM PIPE PHY core. The parameters of both cores should be set in the same manner.

# 5.1.2 Replay Buffer Size

The replay buffer size is determined by three items:

- 1. The value which the device will advertise to the system in the Max Payload Size Supported field of the Device Capabilities register.
- 2. A Replay Buffer Size Multiplication Factor of either 4 or 8 times the Max Payload Size Supported value.
- 3. The setting of the Physical Link Width parameter (see *Section 5.1.1 Physical Link Width* on page 71). This parameter affects the data bus width of the TL\_TX\_DATA bus and therefore the replay buffer's data and address bus widths.

Results of combining the items are shown in *Table 15*, which shows the replay buffer size and the width of the address bus (for x1, x4, x8 and x6 Physical Link Width configurations) to the RAM used as the replay buffer.

#### Table 15. Max\_Payload\_Size versus Replay Buffer Configuration Settings (Page 1 of 2)

Max Payload Size Supported (Bytes)	Multiplication Factor	Replay Buffer Size (Bytes)	RAM Address Bus Width Physical Link Width of x16/x8/x4/x1
128	4	512	5/6/7/7
256	4	1024	6/7/8/8
512	4	2048	7/8/9/9
1024	4	4096	8/9/10/10

#### Table 15. Max\_Payload\_Size versus Replay Buffer Configuration Settings (Page 2 of 2)

Max Payload Size Supported (Bytes)	Multiplication Factor	Replay Buffer Size (Bytes)	RAM Address Bus Width Physical Link Width of x16/x8/x4/x1
2048	4	8192	9/10/11/11
4096	4	16,384	10/11/12/12
128	8	1024	6/7/8/8
256	8	2048	7/8/9/9
512	8	4096	8/9/10/10
1024	8	8192	9/10/11/11
2048	8	16,384	10/11/12/12
4096	8	32,768	11/12/13/13

The parameters that control the Maximum Payload Size Supported setting are:

- PCIEXDLP\_MPSS\_128
- PCIEXDLP\_MPSS\_256
- PCIEXDLP\_MPSS\_512
- PCIEXDLP\_MPSS\_1024
- PCIEXDLP\_MPSS\_2048
- PCIEXDLP\_MPSS\_4096

Only one of these parameters may be defined at any one time.

The Replay Buffer Size Multiplication Factor is controlled by one parameter:

• PCIEXDLP\_REPLAYSIZE\_4X

If the parameter is defined, a multiplication factor of 4 is used. If it is **NOT** defined, a multiplication factor of 8 is used.

Note that the maximum number of TLPs stored in the replay buffer will be either:

- 3 TLPs which contains a payload of the maximum size supported (if a multiplication factor of 4 is selected).
- 7 TLPs which contains a payload of the maximum size supported (if a multiplication factor of 8 is selected).
- 8 TLPs if their combined size (including header, payload, and digest) does not exceed the replay buffer size.

#### 5.1.3 Replay Buffer Read Access Time

The replay buffer read access time may be set to one cycle (default) or two cycles with the parameter:

# PCIEXDLP\_2\_CYCLE\_REPLAY\_ACCESS

If the parameter is defined, the read access time of the replay buffer is set to two cycles. Defining this parameter does not change the data throughput requirement of the replay buffer. See section *Section 4.10 TLP Replay Interface* on page 65 for a full description of the interface requirements.
#### 5.1.4 L0s Entry Timeout Setting

The L0s entry policy is based on the number of symbol times elapsed with no TLPs or DLLPs pending for transmission. The number of symbol times may be set to a value of 10 to 255 symbol times, yielding a timeout of 40 ns to 1020 ns.

The PCIEXDLP\_LOSTIMEOUT parameter controls this setting. It must be set to an 8-bit integer value of 10 to 255.

#### 5.1.5 Use of Synchronous or Asynchronous Set/Reset Flip-Flops

This core's default configuration requires the use of flip-flops that can be set/reset when the PCLK250 clock is not running to ensure correct initialization of the logic while SYS\_RESETN is asserted. Such flip-flops are commonly referred to as asynchronous set/reset flip-flops, and use of them allows the core to support any PIPE compliant PHY.

It is possible, however, that PCLK250 is running when SYS\_RESETN is asserted and therefore asynchronous set/reset flip-flops are not necessary. The core configuration can be changed so that flip-flops without asynchronous set/reset are sufficient for synthesis. The parameter that controls the configuration is:

• PCIEXDLP\_SYNC\_RESET

If the parameter is defined, the core does not require asynchronous set/reset flip-flops.

## 5.2 Synthesis Guidelines

### 5.2.1 User Defined Synthesis and Timing Options

#### 5.2.1.1 Synthesis

The Synopsys Design Compiler synthesis script supplied has one user defined setup option: the wire load model used for net loading estimation. The script should be edited and the wire load model name changed to a wire load that exists in the target library.

### 5.2.1.2 Timing

The Synopsys SDC timing constraints file supplied has one user defined setup option: the amount of clock uncertainty applied to the PCLK250 clock source. This parameter may be used to model clock jitter and/or used to provide additional pre-layout timing margin if necessary. The script should be edited and the parameter changed to a number that is appropriate for the synthesis, timing, and layout methodology used.

The core also contains flip-flop pairs which are used to capture asynchronous input signals. *Table 16* lists the captured signal, the standard synthesized instance names of the capture flip-flops, and the capture clock's name. Correct operation of these flip-flop pairs may be ensured in one of two ways:

- 1. Ensure that the delay from the output of the first flip-flop to the input of the second flip-flop is at most 25% of the capture clock's period.
- 2. Ensure that the two flip-flops are placed next to each other, their clock inputs are connected to the same net with minimum wiring length between them, and there is minimum wiring length between the output of the first and the input of the second.

Table 16. Asynchronous Capture Flip-Flop Pairs in the
---

Signal to be Captured	Flip-Flop Instance Names	Capture Clock
RXELECIDLE[15:0] - core input	U_RXA_LANE_yy/RxElecIdleM1_S0_reg U_RXA_LANE_yy/RxElecIdle_S0_reg yy = lane number	PCLK250
PHYSTATUS - core input	U_TXS/LP/PHYSTATUS1_S0_reg U_TXS/LP/PHYSTATUS2_S0_reg	PCLK250

#### 5.2.2 Clocking

This core operates entirely on a 250 MHz clock (PCLK250) supplied by the PHY. The frequency is 250 MHz +/- 300 ppm, and spread spectrum clocking may be used if desired.

Clock gating may be employed during synthesis of the core if desired.

#### 5.2.3 Flip/Flop Selection

If the PCIEXDLP\_SYNC\_RESET configuration parameter is **not** defined (see *Section 5.1.5 Use of Synchronous or Asynchronous Set/Reset Flip-Flops* on page 73), this core requires flip-flops with the following characteristics:

- Rising-edge triggered.
- At least one flip-flop with an asynchronous reset control input.
- At least one flip-flop with an asynchronous set control input.
- If it exists in the library, at least one flip-flop without asynchronous set or reset control pins.
- All flip/flops must be capable of running with a clock frequency of 250 MHz.

The following flip-flops in the IBM CU11 ASIC library satisfy the above requirements:

- D\_L\_LPH4041\_LPC (asynchronous reset)
- D\_F\_LPH2021\_LPC (asynchronous set)
- D\_F\_LPH0001\_LPC and/or D\_F\_LPH0001 (without asynchronous set or reset)

If the PCIEXDLP\_SYNC\_RESET configuration parameter is defined (see *Section 5.1.5 Use of Synchronous or Asynchronous Set/Reset Flip-Flops* on page 73), this core requires flip-flops with the following characteristics:

- Rising-edge triggered.
- At least one flip-flop without asynchronous set or reset control pins.
- All flip/flops must be capable of running with a clock frequency of 250 MHz.

The following flip-flops in the IBM CU11 ASIC library satisfy the above requirements:

• D\_F\_LPH0001\_LPC and/or D\_F\_LPH0001 (without asynchronous set or reset)

## 5.3 Test Interface Requirements

This core contains no test signals or test logic.

#### Core version 4.02 or later

# 5.4 Physical Design Floorplanning Guidelines

It is likely that the physical area required by the attached PHY will be significantly larger than the area required by this core. As a result, placement of this core will generally be determined by the location of the PHY's PIPE interface pin locations. A typical floor plan might look like the one shown in *Figure 49*.

#### Figure 49. Typical Physical Floor Plan

PCI Express x16 Data Link and Logical Physical
